## 1 Chapter 1

### Divisibility and congruence

**Theorem 1.1.** *Let  $a$ ,  $b$ , and  $c$  be integers. If  $a \mid b$  and  $a \mid c$ , then  $a \mid (b + c)$ .*

*Proof.*

(1.1.1)	$\exists d_b \in \mathbb{Z} \ni b = a \cdot d_b$	because $a \mid b$	
(1.1.2)	$\exists d_c \in \mathbb{Z} \ni c = a \cdot d_c$	because $a \mid c$	
(1.1.3)	$b + c = a \cdot d_b + a \cdot d_c$	by (1.1.1) and (1.1.2)	
(1.1.4)	$b + c = a \cdot (d_b + d_c)$	by distributive property	
(1.1.5)	$d_b + d_c \in \mathbb{Z}$	because $d_b \in \mathbb{Z}$ and $d_c \in \mathbb{Z}$	
	$a \mid (b + c)$	by def'n of divides	□

**Theorem 1.2.** *Let  $a$ ,  $b$ , and  $c$  be integers. If  $a \mid b$  and  $a \mid c$ , then  $a \mid (b - c)$ .*

*Proof.*

(1.2.1)	$\exists d_b \in \mathbb{Z} \ni b = a \cdot d_b$	because $a \mid b$	
(1.2.2)	$\exists d_c \in \mathbb{Z} \ni c = a \cdot d_c$	because $a \mid c$	
(1.2.3)	$b - c = a \cdot d_b - a \cdot d_c$	by (1.2.1) and (1.2.2)	
(1.2.4)	$b - c = a \cdot (d_b - d_c)$	by distributive property	
(1.2.5)	$d_b - d_c \in \mathbb{Z}$	because $d_b \in \mathbb{Z}$ and $d_c \in \mathbb{Z}$	
	$a \mid (b - c)$	by def'n of divides	□

**Theorem 1.3.** *Let  $a$ ,  $b$ , and  $c$  be integers. If  $a \mid b$  and  $a \mid c$ , then  $a \mid bc$ .*

*Proof.*

(1.3.1)	$\exists d_b \in \mathbb{Z} \ni b = a \cdot d_b$	because $a \mid b$	
(1.3.2)	$\exists d_c \in \mathbb{Z} \ni c = a \cdot d_c$	because $a \mid c$	
(1.3.3)	$bc = (a \cdot d_b) \cdot (a \cdot d_c)$	by (1.3.1) and (1.3.2)	
(1.3.4)	$bc = a \cdot (a \cdot d_b \cdot d_c)$	by associativity and commutativity	
(1.3.5)	$a \cdot d_b \cdot d_c \in \mathbb{Z}$	because $d_b \in \mathbb{Z}$ and $d_c \in \mathbb{Z}$	
	$a \mid bc$	by def'n of divides	□

**Question 1.4.** *Can you weaken the hypothesis of the previous theorem and still prove the conclusion? Can you keep the same hypothesis, but replace the conclusion by the stronger conclusion that  $a^2 \mid bc$  and still prove the theorem?*

Yes. You can remove the  $a \mid c$  condition to weaken the hypothesis, or with both  $a \mid b$  and  $a \mid c$  you can show  $a^2 \mid bc$ .

**Question 1.5.** Can you formulate your own conjecture along the lines of the above theorems and then prove it to make it your theorem?

Yes.

**Paul's Conjecture 1.** Let  $a$ ,  $b$ , and  $c$  be integers. If  $a|b$  and  $a|c$ , then  $a^2|bc$ .

*Proof.* First, take lines (1.3.1) through (1.3.4) of the proof of Theorem 1.3. Then,

$$\begin{array}{ll} d_b \cdot d_c \in \mathbb{Z} & \text{because } d_b \in \mathbb{Z} \text{ and } d_c \in \mathbb{Z} \\ a^2|bc & \text{by def'n of divides} \end{array} \quad \square$$

**Theorem 1.6.** Let  $a$ ,  $b$ , and  $c$  be integers. If  $a|b$ , then  $a|bc$ .

*Proof.*

$$\begin{array}{lll} (1.6.1) & \exists d \in \mathbb{Z} \ni ad = b & \text{because } a|b \\ (1.6.2) & bc = adc & \text{by (1.6.1)} \\ (1.6.3) & dc \in \mathbb{Z} & \text{because } d \in \mathbb{Z} \text{ and } c \in \mathbb{Z} \\ & a|bc & \text{by def'n of divides} \end{array} \quad \square$$

**Exercise 1.7.** Answer each of the following questions, and prove that your answer is correct.

1. Is  $45 \equiv 9 \pmod{4}$ ?  
Yes.  $4 \cdot 9 = 36 = 45 - 9$ .
2. Is  $37 \equiv 2 \pmod{5}$ ?  
Yes.  $5 \cdot 7 = 35 = 37 - 2$ .
3. Is  $37 \equiv 3 \pmod{5}$ ?  
No.  $37 - 3 = 34$  which is not a multiple of 5.
4. Is  $37 \equiv -3 \pmod{5}$ ?  
Yes.  $5 \cdot 8 = 40 = 37 - (-3)$ .

**Exercise 1.8.** For each of the following congruences, characterize all the integers  $m$  that satisfy that congruence.

1.  $m \equiv 0 \pmod{3}$   
 $m \in \{3z \mid z \in \mathbb{Z}\}$
2.  $m \equiv 1 \pmod{3}$   
 $m \in \{3z + 1 \mid z \in \mathbb{Z}\}$
3.  $m \equiv 2 \pmod{3}$   
 $m \in \{3z + 2 \mid z \in \mathbb{Z}\}$
4.  $m \equiv 3 \pmod{3}$   
 $m \in \{3z \mid z \in \mathbb{Z}\}$
5.  $m \equiv 4 \pmod{3}$   
 $m \in \{3z + 1 \mid z \in \mathbb{Z}\}$

**Theorem 1.9.** Let  $a$  and  $n$  be integers with  $n > 0$ . Then  $a \equiv a \pmod{n}$ .

*Proof.*

(1.9.1)	$0 \in \mathbb{Z}$	
(1.9.2)	$n \cdot 0 = 0$	
(1.9.3)	$n 0$	By def'n of divides
(1.9.4)	$a - a = 0$	
(1.9.5)	$n (a - a)$	By (1.9.3) and (1.9.4)
	$a \equiv a \pmod{n}$	By def'n of modular congruence <span style="float: right;">□</span>

**Theorem 1.10.** Let  $a$ ,  $b$ , and  $n$  be integers with  $n > 0$ . If  $a \equiv b \pmod{n}$ , then  $b \equiv a \pmod{n}$ .

*Proof.*

(1.10.1)	$a \equiv b \pmod{n}$	Given
(1.10.2)	$\exists d \in \mathbb{Z} \ni nd = a - b$	By def'n of modular congruence
(1.10.3)	$-1nd = -1 \cdot (a - b)$	By multiplicative property of equality
(1.10.4)	$n \cdot (-d) = b - a$	By various algebra
(1.10.5)	$-d \in \mathbb{Z}$	By multiplicative closure of $\mathbb{Z}$
(1.10.6)	$n (b - a)$	By (1.10.4), (1.10.5)
	$b \equiv a \pmod{n}$	By def'n of modular congruence <span style="float: right;">□</span>

**Theorem 1.11.** Let  $a$ ,  $b$ , and  $n$  be integers with  $n > 0$ . If  $a \equiv b \pmod{n}$  and  $b \equiv c \pmod{n}$ , then  $a \equiv c \pmod{n}$ .

*Proof.*

(1.11.1)	$n a - b$	By $a \equiv b \pmod{n}$
(1.11.2)	$n b - c$	By $b \equiv c \pmod{n}$
(1.11.3)	$\exists d_1 \in \mathbb{Z} \ni nd_1 = a - b$	By (1.11.1)
(1.11.4)	$\exists d_2 \in \mathbb{Z} \ni nd_2 = b - c$	By (1.11.2)
(1.11.5)	$nd_1 + nd_2 = (a - b) + (b - c)$	By additive property of equality
(1.11.6)	$n(d_1 + d_2) = a - c$	By various algebra
(1.11.7)	$d_1 + d_2 \in \mathbb{Z}$	By closure of integers under addition
(1.11.8)	$n (a - c)$	By def'n of divides
	$a \equiv c \pmod{n}$	By def'n of modular congruence <span style="float: right;">□</span>

**Theorem 1.12.** Let  $a$ ,  $b$ ,  $c$ ,  $d$ , and  $n$  be integers with  $n > 0$ . If  $a \equiv b \pmod{n}$  and  $c \equiv d \pmod{n}$ , then  $a + c \equiv b + d \pmod{n}$ .

*Proof.*

(1.12.1)	$n (a - b)$	By $a \equiv b \pmod{n}$
(1.12.2)	$\exists d_1 \in \mathbb{Z} \ni nd_1 = a - b$	By def'n divides
(1.12.3)	$n (c - d)$	By $c \equiv d \pmod{n}$
(1.12.4)	$\exists d_2 \in \mathbb{Z} \ni nd_2 = c - d$	By def'n divides
(1.12.5)	$nd_1 + nd_2 = (a - b) + (c - d)$	By additive property of equality
(1.12.6)	$n \cdot (d_1 + d_2) = (a + c) - (b + d)$	By various algebra
(1.12.7)	$d_1 + d_2 \in \mathbb{Z}$	By additive closure of $\mathbb{Z}$
(1.12.8)	$n ((a + c) - (b + d))$	By def'n of divides
	$a + c \equiv b + d \pmod{n}$	By def'n of modular congruence <span style="float: right;">□</span>

**Theorem 1.13.** Let  $a, b, c, d$ , and  $n$  be integers with  $n > 0$ . If  $a \equiv b \pmod{n}$  and  $c \equiv d \pmod{n}$ , then  $a - c \equiv b - d \pmod{n}$ .

*Proof.* Notice  $-c$  and  $-d$  are integers, and  $-c \equiv -d \pmod{n}$  (glossing over the proof of that for now). Then simply cite 1.12 and we're done.  $\square$

**Theorem 1.14.** Let  $a, b, c, d$ , and  $n$  be integers with  $n > 0$ . If  $a \equiv b \pmod{n}$  and  $c \equiv d \pmod{n}$ , then  $ac \equiv bd \pmod{n}$ .

*Proof.*

$$\begin{array}{lll}
(1.14.1) & n|(a-b) & \text{By } a \equiv b \pmod{n} \\
(1.14.2) & \exists k_1 \in \mathbb{Z} \ni a-b = nk_1 & \\
(1.14.3) & a = nk_1 + b & \\
(1.14.4) & n|(c-d) & \text{By } c \equiv d \pmod{n} \\
(1.14.5) & \exists k_2 \in \mathbb{Z} \ni c-d = nk_2 & \\
(1.14.6) & c = nk_2 + d & \\
(1.14.7) & ac = (nk_1 + b)(nk_2 + d) & \text{By (1.14.3) and (1.14.6)} \\
(1.14.8) & ac = n^2k_1k_2 + nk_1d + nk_2b + bd & \\
(1.14.9) & ac - bd = n \cdot (nk_1k_2 + k_1d + k_2b) & \\
(1.14.10) & n|(ac - bd) & \text{Since } nk_1k_2 + k_1d + k_2b \in \mathbb{Z} \\
& ac \equiv bd \pmod{n} & \square
\end{array}$$

**Exercise 1.15.** Let  $a, b$ , and  $n$  be integers with  $n > 0$ . Show that if  $a \equiv b \pmod{n}$ , then  $a^2 \equiv b^2 \pmod{n}$ .

*Proof.*

$$\begin{array}{lll}
(1.15.1) & a \equiv b \pmod{n} & \text{Given} \\
(1.15.2) & a \cdot a \equiv b \cdot b \pmod{n} & 1.14 \\
& a^2 \equiv b^2 \pmod{n} & \square
\end{array}$$

**Exercise 1.16.** Let  $a, b$ , and  $n$  be integers with  $n > 0$ . Show that if  $a \equiv b \pmod{n}$ , then  $a^3 \equiv b^3 \pmod{n}$ .

*Proof.*

$$\begin{array}{lll}
(1.16.1) & a \equiv b \pmod{n} & \text{Given} \\
(1.16.2) & a^2 \equiv b^2 \pmod{n} & 1.15 \\
(1.16.3) & a \cdot a^2 \equiv b \cdot b^2 \pmod{n} & \text{By 1.14 on (1.16.1) and (1.16.2)} \\
& a^3 \equiv b^3 \pmod{n} & \square
\end{array}$$

**Exercise 1.17.** Let  $a, b, k$ , and  $n$  be integers with  $n > 0$  and  $k > 1$ . Show that if  $a \equiv b \pmod{n}$  and  $a^{k-1} \equiv b^{k-1} \pmod{n}$ , then  $a^k \equiv b^k \pmod{n}$ .

*Proof.*

$$\begin{array}{lll}
(1.17.1) & a \equiv b \pmod{n} & \text{Given} \\
(1.17.2) & a^{k-1} \equiv b^{k-1} \pmod{n} & 1.15 \\
(1.17.3) & a \cdot a^{k-1} \equiv b \cdot b^{k-1} \pmod{n} & \text{By 1.14 on (1.17.1) and (1.17.2)} \\
& a^k \equiv b^k \pmod{n} & \square
\end{array}$$

**Theorem 1.18.** Let  $a, b, k$ , and  $n$  be integers with  $n > 0$  and  $k > 0$ . If  $a \equiv b \pmod{n}$ , then  $a^k \equiv b^k \pmod{n}$ .

*Proof.* Our base case is 1.9. Our induction hypothesis is " $a, b, k$ , and  $n$  are integers with  $n > 0$  and  $k > 1$  such that  $\forall j \ni 0 < j < k$ , we find  $a^j \equiv b^j \pmod{n}$ ". Notice our induction hypothesis fulfills the criteria for 1.17, and in fact 1.17 covers our induction step.  $\square$

**Exercise 1.19.** Illustrate each of Theorems 1.12 - 1.18 with an example using actual numbers

1.12

$2 \equiv 12 \pmod{10}$  and  $5 \equiv 15 \pmod{10}$  imply  $7 \equiv 27 \pmod{10}$ .

1.13

$7 \equiv 27 \pmod{10}$  and  $12 \equiv 2 \pmod{10}$  imply that  $-5 \equiv 25 \pmod{10}$ .

1.14

$2 \equiv 7 \pmod{5}$  and  $3 \equiv 8 \pmod{5}$  imply that  $6 \equiv 56 \pmod{5}$ .

1.15

$2 \equiv 7 \pmod{5}$  implies that  $4 \equiv 49 \pmod{5}$ .

1.16

$1 \equiv 3 \pmod{2}$  implies that  $1 \equiv 27 \pmod{2}$ .

1.17

$1 \equiv 3 \pmod{2}$  and  $1 \equiv 27 \pmod{2}$  imply that  $1 \equiv 81 \pmod{2}$ .

1.18

$1 \equiv 3 \pmod{2}$  implies that  $1 \equiv 81 \pmod{2}$ .

**Question 1.20.** Let  $a, b, c$ , and  $n$  be integers for which  $ac \equiv bc \pmod{n}$ . Can we conclude that  $a \equiv b \pmod{n}$ ? If you answer "yes", try to give a proof. If you answer "no", try to give a counterexample.

No. Notice  $1 \cdot 0 \equiv 2 \cdot 0 \pmod{5}$  and yet  $1 \not\equiv 2 \pmod{5}$ .

**Theorem 1.21.** Let a natural number  $n$  be expressed in base 10 as

$$n = a_k a_{k-1} \dots a_1 a_0$$

If  $m = a_k + a_{k-1} + \dots + a_1 + a_0$  then  $n \equiv m \pmod{3}$ .

First, a Lemma that will help us later.

**Lemma 1.21.1.** Let  $a$  be an integer and  $j$  a natural number. Then  $a \equiv a \cdot 10^j \pmod{3}$ .

*Proof.* Notice that  $1 \equiv 10 \pmod{3}$ . Then, by 1.18, we find  $1^j \equiv 10^j \pmod{3}$  and thus that  $1 \equiv 10^j \pmod{3}$ . Then, since  $a \equiv a \pmod{3}$  (by 1.9), we invoke 1.14 to find  $a \cdot 1 \equiv a \cdot 10^j \pmod{3}$ , implying that  $a \equiv a \cdot 10^j \pmod{3}$ .  $\square$

Now we begin our proof of the theorem in full.

*Proof.* Notice that  $n$  can be written as  $a_k \cdot 10^k + a_{k-1} \cdot 10^{k-1} + \dots + a_1 \cdot 10 + a_0$ , or more easily as

$$n = \sum_{i=0}^k a_i \cdot 10^i$$

Now notice that

$$m = \sum_{i=0}^k a_i$$

By 1.21.1, we notice that  $\forall i, a_i \equiv a_i \cdot 10^i \pmod{3}$ . Thus,  $n$  and  $m$  are sums of terms that are congruent modulo 3. By repeatedly invoking 1.12, we eventually find that the two strings of congruent sums are themselves congruent, i.e. that  $n \equiv m \pmod{3}$ .  $\square$

**Theorem 1.22.** If a natural number is divisible by 3, then, when expressed in base 10, the sum of its digits is divisible by 3.

*Proof.* Let the natural number be  $n$ , and the sum of its digits  $m$ . We're given by the theorem  $n \equiv 0 \pmod{3}$ , and by 1.21 we know  $n \equiv m \pmod{3}$ , so we can cite 1.11 and conclude  $m \equiv 0 \pmod{3}$ , i.e.  $m$  is divisible by 3.  $\square$

**Theorem 1.23.** *If the sum of the digits of a natural number expressed in base 10 is divisible by 3, then the number is divisible by 3 as well.*

*Proof.* Let the natural number be  $n$ , and the sum of its digits  $m$ . We're given by the theorem  $m \equiv 0 \pmod{3}$ , and by 1.21 we know  $n \equiv m \pmod{3}$ , so we can cite 1.11 and conclude  $n \equiv 0 \pmod{3}$ , i.e.  $n$  is divisible by 3.  $\square$

**Exercise 1.24.** *Devise and prove other divisibility criteria similar to the preceding one.*

A number is divisible by 2 if and only if its last digit is divisible by 2, because any (base 10) number  $n = a_k a_{k-1} \dots a_1 a_0 = a_k a_{k-1} \dots a_1 \cdot 10 + a_0$ , and  $2|10$  so  $2|\dots \cdot 10$ . Thus,  $2|\dots \cdot 10 + a_0$  iff  $2|a_0$ .

Similar proofs can be done for 5 and the last digit, 4 and the last 2 digits, 8 and the last 3 digits, 16 and the last 4 digits, 32 and the last 5 digits, etc.

## The Division Algorithm

**Exercise 1.25.** *Illustrate the division algorithm for:*

1.  $m = 25, n = 7$ .  
 $25 = 7 \cdot 3 + 4$ .
2.  $m = 277, n = 4$ .  
 $277 = 4 \cdot 69 + 1$ .
3.  $m = 33, n = 11$ .  
 $33 = 11 \cdot 3 + 0$ .
4.  $m = 33, n = 45$ .  
 $33 = 44 \cdot 0 + 33$ .

**Theorem 1.26.** *Prove the existence part of the Division Algorithm. In other words, given natural numbers  $n$  and  $m$ , show there exist integers  $q$  and  $r$  such that  $m = nq + r$  and  $0 \leq r \leq n - 1$ .*

*Proof.* Let  $S = \{x \in \mathbb{Z} \mid nx > m\}$ . By the Well-Ordering Axiom,  $S$  has a smallest element: call it  $s$ . Let  $q = s - 1$ . This definition gives us two important properties:

1.  $nq \leq m$ , for if  $nq > m$  then  $q \in S$  with  $q < s$ , which is impossible since  $s$  is the smallest element of  $S$ .
2.  $m < n(q + 1) = nq + n$ , for  $q + 1 = s$  and  $sx > m$  because  $s \in S$ .

Now, we define  $r = m - nq$ , so that by definition  $m = nq + r$ . Since  $nq \leq m$ , we know  $r \geq 0$ . Since  $m < nq + n$ , and yet  $m = nq + r$ , implying  $nq + r < nq + n \implies r < n \implies r \leq n - 1$ .

Thus, we have found  $q, r$  such that  $m = nq + r$  and  $0 \leq r \leq n - 1$ .  $\square$

**Theorem 1.27.** *Prove the uniqueness part of the Division Algorithm. In other words, given natural numbers  $n$  and  $m$ , if there are 4 integers  $q, q', r$ , and  $r'$ , such that  $m = nq + r = nq' + r'$  with  $0 \leq r, r' \leq n - 1$  then  $q = q'$  and  $r = r'$ .*

*Proof.* Notice that  $nq + r = nq' + r'$  implies that  $nq - nq' = r' - r \implies n(q - q') = r' - r$ .

Since  $0 \leq r, r' \leq n - 1$ , we conclude that  $-n + 1 \leq r' - r \leq n - 1$ . By our previous equality, then,  $-n + 1 \leq n(q - q') \leq n - 1 \implies -n < n(q - q') < n$ . Since  $n$  is a natural number, we can divide by  $n$  to get  $-1 < q - q' < 1$ . Since  $q$  and  $q'$  are integers,  $q - q'$  must also be an integer. The only integer between  $-1$  and  $1$  is  $0$ , so we conclude  $q - q' = 0 \implies q = q'$ .

Once we have  $q = q'$ , we see that  $nq + r = nq' + r' \implies nq + r = nq + r' \implies r = r'$ .  $\square$

**Theorem 1.28.** Let  $a$ ,  $b$ , and  $n$  be integers with  $n > 0$ . Then  $a \equiv b \pmod{n}$  if and only if  $a$  and  $b$  have the same remainder when divided by  $n$ . Equivalently,  $a \equiv b \pmod{n}$  if and only if when  $a = nq_1 + r_1$  ( $0 \leq r_1 \leq n - 1$ ) and  $b = nq_2 + r_2$  ( $0 \leq r_2 \leq n - 1$ ) then  $r_1 = r_2$ .

First, we will show that  $a \equiv b \pmod{n} \implies r_1 = r_2$ .

*Proof.* Notice by the definition of modular congruence that  $a \equiv b \pmod{n}$  implies that  $n \mid (b - a)$ , or  $\exists d \in \mathbb{Z} \ni nd = b - a$ . Using  $a = nq_1 + r_1$  and  $b = nq_2 + r_2$  we get  $nd = nq_1 + r_1 - nq_2 - r_2 = n(q_1 - q_2) + r_1 - r_2$ . Then we get  $nd - n(q_1 - q_2) = r_1 - r_2$  or  $n(d - q_1 + q_2) = r_1 - r_2$ .

Since  $0 \leq r_1, r_2 \leq n - 1$  we find that  $-n + 1 \leq r_1 - r_2 \leq n - 1 \implies -n < r_1 - r_2 < n$ . Using our previous equation with  $r_1 - r_2$  we get that  $-n < n(d - q_1 + q_2) < n$ , and dividing by  $n$  (which we can do because  $n > 0$ ) we get  $-1 < d - q_1 + q_2 < 1$ . Since  $d$ ,  $q_1$ , and  $q_2$  are all integers,  $d - q_1 + q_2$  is also an integer, and the only integer between  $-1$  and  $1$  is  $0$  so we find  $d - q_1 + q_2 = 0$ .

Plugging this back in to  $n(d - q_1 + q_2) = r_1 - r_2$ , we find  $n \cdot 0 = r_1 - r_2$ , which implies  $0 = r_1 - r_2$ , or  $r_1 = r_2$ .  $\square$

Second, we will show that  $r_1 = r_2 \implies a \equiv b \pmod{n}$ .

*Proof.* Notice  $a - b = nq_1 + r_1 - (nq_2 + r_2)$ . With some simple rearranging, we obtain  $a - b = n(q_1 - q_2) + r_1 - r_2$ . Since we know  $r_1 = r_2$ , we know  $r_1 - r_2 = 0$ , and plugging this in we obtain  $a - b = n(q_1 - q_2)$ .

Since  $q_1$  and  $q_2$  are integers,  $q_1 - q_2$  is also an integer. Thus,  $n$  times some integer is  $a - b$ : in other words,  $n \mid (a - b)$ .

Then, by the definition of modular congruence, we obtain  $a \equiv b \pmod{n}$ .  $\square$

## Greatest common divisors and linear Diophantine equations

**Question 1.29.** Do every two integers have at least one common divisor?

Yes. For any two integers  $a$  and  $b$ ,  $1 \cdot a = a$  and  $1 \cdot b = b$  so  $1 \mid a$  and  $1 \mid b$ , making  $1$  a common divisor of  $a$  and  $b$ .

**Question 1.30.** Can two integers have infinitely many common divisors?

No, if the two integers are distinct. Any nonzero integer  $n$  can only have finitely many divisors, as any integer  $d$  such that  $d < -|n|$  or  $d > |n|$  cannot be a divisor (since  $1d$  and  $-1d$  have a greater absolute value than  $n$ , and  $0d = 0 \neq n$ ). In other words, only the numbers  $f$  such that  $-n \leq f \leq n$  are “eligible” to be divisors of  $n$ , so there can only be finitely many divisors of  $n$ .

**Exercise 1.31.** Find the following greatest common divisors. Which pairs are relatively prime?

1.  $(36, 22)$   
2
2.  $(45, -15)$   
15
3.  $(-296, -88)$   
8
4.  $(0, 256)$   
256
5.  $(15, 28)$   
1 (relatively prime)
6.  $(1, -2436)$   
1 (relatively prime)

**Theorem 1.32.** Let  $a$ ,  $n$ ,  $b$ ,  $r$ , and  $k$  be integers. If  $a = nb + r$  and  $k \mid a$  and  $k \mid b$ , then  $k \mid r$ .

*Proof.* Let  $a = d_a k$  and  $b = d_b k$ , where  $d_a$  and  $d_b$  are the integers guaranteed by the facts that  $k \mid a$  and  $k \mid b$ . Then, we have  $d_a k = nd_b k + r$ . Isolating  $r$ , we get  $r = d_a k - nd_b k = k(d_a - nd_b)$ . Since  $n$ ,  $d_a$ , and  $d_b$  are all integers, we know  $d_a - nd_b$  is an integer. Thus, we’ve found  $r$  is equal to  $k$  times some integer, so  $k \mid r$ .  $\square$

**Theorem 1.33.** Let  $a, b, n_1$ , and  $r_1$  be integers with  $a$  and  $b$  not both 0. If  $a = n_1b + r_1$ , then  $(a, b) = (b, r_1)$ .

*Proof.* We will show that the common divisors of  $a$  and  $b$  are the same as the common divisors of  $b$  and  $r_1$ , and thus conclude that the greatest element of  $S$  is also the greatest element of  $T$ .

Let  $S$  be the set of common divisors of  $a$  and  $b$ , and let  $T$  be the set of common divisors of  $b$  and  $r_1$ . We will show  $S = T$  by double inclusion.

First, let's show  $S \subset T$ . Take an arbitrary  $s \in S$ . Since  $s|a$  and  $s|b$ , we conclude  $\exists d_a, d_b \in \mathbb{Z} \ni a = sd_a, b = sd_b$ . We can then rearrange  $a = n_1b + r_1$  to read  $r_1 = a - n_1b$ , and then plug in our previous two equations to get  $r_1 = sd_a - n_1sd_b \implies r_1 = s(d_a - n_1d_b)$ . Since  $d_a, d_b$ , and  $n_1$  are all integers, we know  $d_a - n_1d_b$  is an integer, thus implying that  $s|r_1$ . Since we know  $s|b$  since  $s \in S$ , we conclude  $s \in T$ . Thus, any arbitrary  $s \in S$  is an element of  $T$ , so  $S \subset T$ .

Showing that  $T \subset S$  proceeds in much the same way. Take  $t \in T$ , conclude since  $t|b$  and  $t|r_1$  we find  $\exists d_b, d_r \in \mathbb{Z} \ni b = td_b, r_1 = td_r$ , and then plug those in to  $a = n_1b + r_1$  to get  $a = n_1td_b + td_r \implies a = t(n_1d_b + d_r)$ . Since  $n_1, d_b$ , and  $d_r$  are integers, we find  $t|a$ , and since  $t|b$  because  $t \in T$ , we thus conclude  $t \in S$ . Thus any arbitrary  $t \in T$  is an element of  $S$ , so  $T \subset S$ .

Thus, by double inclusion,  $S = T$ . This implies that the greatest element of  $S$ , i.e.  $(a, b)$ , is equal to the greatest element of  $T$ , i.e.  $(b, r_1)$ .  $\square$

**Exercise 1.34.** Use the preceding theorem to show that if  $a = 51$  and  $b = 15$ , then  $(51, 15) = (6, 3) = 3$ .

*Proof.* Since  $51 = 3 \cdot 15 + 6$ , we find  $(51, 15)$ , we cite 1.33 to see  $(51, 15) = (15, 6)$ . Then, since  $15 = 2 \cdot 6 + 3$ , we again cite 1.33 to find  $(15, 6) = (6, 3)$ . We see that  $(6, 3) = 3$  by inspection. Then, since equality is transitive, we conclude  $(51, 15) = (6, 3) = 3$ .  $\square$

**Exercise 1.35.** Using the previous theorem and the Division Algorithm successively, devise a procedure for finding the greatest common divisor of two integers.

Well you kind of gave the game away when you said to use 1.33 and the division algorithm successively huh. If you're trying to find  $(a, b)$ , you simply invoke the division algorithm to get  $a = nb + r$  (assuming WLOG that  $a \geq b$ ), and then rewrite  $(a, b)$  as  $(b, r)$ . Then, you use the division algorithm to get  $b = nr + r'$ , simplifying to  $(r, r')$ , etc., until at some point you have  $(x, 0)$ , which by inspection is equal to  $x$ .

You will always reach  $(x, 0)$  because the division algorithm produces a remainder  $r$  that is strictly less than the smaller input  $b$ , so (informally) the smaller of the two numbers you're working with always gets smaller while never going negative.

**Exercise 1.36.** Use the Euclidean Algorithm to find the following.

1.  $(96, 112)$

$112 = 1 \cdot 96 + 16$ , simplifying the problem to  $(96, 16)$ . Then  $96 = 5 \cdot 16 + 0$ , so we get  $(16, 0) = 16$

2.  $(162, 31)$

$162 = 5 \cdot 31 + 7 \implies (31, 7) \implies 31 = 4 \cdot 7 + 3 \implies (7, 3) \implies 7 = 2 \cdot 3 + 1 \implies (3, 1) = 1$ .

3.  $(0, 256)$

Since everything divides 0, this is trivially 256.

4.  $(-288, -166)$

$-166 = 1 \cdot -288 + 122 \implies (-288, 122) \implies -288 = -3 \cdot 122 + 78 \implies (122, 78) \implies 122 = 1 \cdot 78 + 44 \implies (78, 44) \implies 78 = 1 \cdot 44 + 34 \implies (44, 34) \implies 44 = 1 \cdot 34 + 10 \implies (34, 10) = 2$  by inspection.

5.  $(1, -2436)$

Since the only integers that divide 1 are  $-1, 0$ , and  $1$ , we trivially find 1.

**Exercise 1.37.** Find integers  $x$  and  $y$  such that  $162x + 31y = 1$ .

By division algorithm,  $162 = 5 \cdot 31 + 7 \implies 7 = 1 \cdot 162 + (-5) \cdot 31$ .

By division algorithm,  $31 = 4 \cdot 7 + 3 \implies 3 = 1 \cdot 31 + (-4) \cdot 7 = 1 \cdot 31 + (-4) \cdot (1 \cdot 162 + (-5) \cdot 31) = (-4) \cdot 162 + 21 \cdot 31$ .

By division algorithm,  $7 = 2 \cdot 3 + 1 \implies 1 = 1 \cdot 7 + (-2) \cdot 3 = 1 \cdot (1 \cdot 162 + (-5) \cdot 31) + (-2) \cdot ((-4) \cdot 162 + 21 \cdot 31) = 9 \cdot 162 + (-47) \cdot 31$ .

Thus, we've found our solution  $x = 9$  and  $y = -47$ .

**Theorem 1.38.** *Let  $a$  and  $b$  be integers. If  $(a, b) = 1$ , then there exist integers  $x$  and  $y$  such that  $ax + by = 1$ .*

*Proof.* If either  $a$  or  $b$  is negative, replace it with  $-a$  or  $-b$  for the rest of this proof. At then end, you can replace either  $x$  or  $y$  with  $-x$  or  $-y$  to get an answer; for instance, if  $a = -3$ , we can replace  $a = 3$ , do the proof to obtain  $x_0$  and  $y_0$  such that  $3x_0 + by_0 = 1$  and then realize that  $(-3)(-x_0) + by_0 = 1$ , which since  $-x_0$  is still an integer still suffices. Now we will only be worrying about non-negative  $a$  and  $b$ s.

We will demonstrate an algorithm to find  $x$  and  $y$ . WLOG, assume  $a \geq b$ . Invoke the division algorithm to get  $a = n_1b + r_1$ . Then invoke it again to get  $b = n_2r_1 + r_2$ . Then invoke it again to get  $r_1 = n_3r_2 + r_3$ . Etc. etc. etc.

We will show that the series “remainder” generated by this algorithm eventually has to hit 0: in other words,  $\exists i \in \mathbb{N} \ni r_i = 0$ . To do this, we must notice that for any index  $j$ , since  $r_j$  is generated by calling the division algorithm on  $r_{j-2}$  and  $r_{j-1}$ , we find that  $r_j \leq r_{j-1} - 1$ . Notice, then, that we can apply this to  $r_{j-1}$  to obtain  $r_{j-1} \leq r_{j-2} - 1$ , and then plug that in to our previous inequality to get  $r_j \leq r_{j-1} - 1 \leq r_{j-2} - 2$ .

By inspection (i.e. I’m lazy and don’t want to formalize this), we notice we can continually apply this. We will apply this to  $r_b$ , and notice that  $r_b \leq r_{b-1} - 1 \leq r_{b-2} - 2 \leq \dots \leq r_1 - (b-1) \leq b - b$ . Since  $b - b = 0$ , we find  $r_b \leq 0$ , but since  $r_b$  is a remainder from the division algorithm we know  $r_b \geq 0$ , so we conclude  $r_b = 0$ .

Notice we have *not* proven that  $r_b$  is the *first* 0, only that the remainders must *eventually* reach 0 at *some* point.

Now, keep invoking the division algorithm until the “remainder” generated by the algorithm is 0: we will label that step  $k + 1$ , so that we find  $r_{k+1} = n_{k+1}r_k + 0$ . We will show that  $r_k$  is 1.

By invoking 1.33 repeatedly, we find that  $(a, b) = (b, r_1) = (r_1, r_2) = \dots = (r_{k-1}, r_k) = (r_k, r_{k+1})$ . Since  $r_{k+1} = 0$ , we conclude  $(a, b) = (r_k, 0)$ . Since 0 divides everything,  $(r_k, 0) = r_k$ , so  $(a, b) = r_k$ , and since  $a$  and  $b$  are relatively prime we conclude  $1 = r_k$ .

Now, we take all of our equations and rewrite them to solve for the remainder. For example,  $a = n_1b + r_1$  becomes  $r_1 = a + (-n_1)b$ , and  $b = n_2r_1 + r_2$  becomes  $r_2 = b + (-n_2)r_1$ .

This gives us a bunch of equations of the form  $r_j = \delta_j r_{j-2} + \gamma_j r_{j-1}$ . This includes one for  $r_k$ , namely  $r_k = \delta_k r_{k-2} + \gamma_k r_{k-1}$ . We can then substitute in lower indices of  $r$  for  $r_{k-2}$  and  $r_{k-1}$ , using the generic equation, to get something like  $r_k = \delta_k(\delta_{k-2}r_{k-4} + \gamma_{k-2}r_{k-3}) + \gamma_k(\delta_{k-1}r_{k-3} + \gamma_{k-1}r_{k-2})$ .

That looks horrifying, but the important bit is that we notice if we simplify it we get  $r_k = Ar_{k-4} + Br_{k-3} + Cr_{k-2}$  with  $A, B, C \in \mathbb{Z}$ . That is, *by replacing all  $r_j$ ’s with their respective equations, we have reduced the highest index on an  $r$  in the right hand side by 1*. Previously, the highest index was  $k - 1$ , but now it’s  $k - 2$ , because we had an equation to represent  $r_{k-1}$  in terms of  $r_{k-3}$  and  $r_{k-4}$ .

Notice, though, that not all  $r$ ’s satisfy this property: namely,  $r_1$  and  $r_2$  simplify down to  $a$  and  $b$ , which then don’t have equations of their own. So, we apply the equations for  $r_k$  through  $r_1$  in “reverse” order, pairing down the maximum index of  $k$  each time, until we’re left with only  $r_1$ ’s and  $r_2$ ’s on the left hand side and can apply those equations to get a linear expression in  $a$  and  $b$  on the right hand side.

We’ve been talking a lot about the right hand side, but remember, the left hand side is  $r_k$ , and we’ve shown  $r_k = 1$ , so we’ve just found a linear expression in  $a$  and  $b$  that is equal to 1. In other words,  $1 = ax + by$  for some  $x, y \in \mathbb{Z}$ .  $\square$

**Theorem 1.39.** *Let  $a$  and  $b$  be integers. If there exist integers  $x$  and  $y$  with  $ax + by = 1$ , then  $(a, b) = 1$ .*

*Proof.* Readers of the last proof will be glad to hear this one is much simpler.

By definition,  $(a, b) | a$  and  $(a, b) | b$ . Then,  $(a, b) | ax$  and  $(a, b) | by$  by 1.6. Then,  $(a, b) | ax + by$  by 1.1. Then, since  $ax + by = 1$ , we find  $(a, b) | 1$ . We know  $1 | a$  and  $1 | b$ , so  $(a, b) \geq 1$ . The only number  $\geq 1$  that divides 1 is 1, so since  $(a, b) \geq 1$  and  $(a, b) | 1$  we conclude  $(a, b) = 1$ .  $\square$

**Theorem 1.40.** *For any integers  $a$  and  $b$  not both 0, there are integers  $x$  and  $y$  such that  $ax + by = (a, b)$ .*

*Proof.* Let  $c = a/(a, b)$  and  $d = b/(a, b)$ . Notice that since  $(c, d) | c$  and  $a = c \cdot (a, b)$  we find  $((c, d) \cdot (a, b)) | a$ , and similarly since  $(c, d) | d$  and  $b = d \cdot (a, b)$  we find  $((c, d) \cdot (a, b)) | b$ .

Since  $c$  and  $d$  are integers not both 0,  $(c, d)$  must be a positive integer. Since  $(c, d) \cdot (a, b)$  is a common factor of  $a$  and  $b$ , and  $(a, b)$  is the *greatest* common factor of  $a$  and  $b$ , we find  $(c, d) \cdot (a, b) \leq (a, b) \implies (c, d) = 1$ .

Thus, we invoke 1.38 to find integers  $x$  and  $y$  such that  $cx + dy = 1$ . Then, we multiply both sides by  $(a, b)$  to find that  $(a, b) \cdot cx + (a, b) \cdot dy = (a, b)$ . Since  $a = (a, b) \cdot c$  and  $b = (a, b) \cdot d$  we conclude  $ax + by = (a, b)$ .  $\square$

**Theorem 1.41.** Let  $a$ ,  $b$ , and  $c$  be integers. If  $a|bc$  and  $(a, b) = 1$ , then  $a|c$ .

*Proof.* Since  $(a, b) = 1$ , we can invoke 1.38 to find  $x, y \in \mathbb{Z} \ni ax + by = 1$ .

Now, since  $a|bc$ , we can cite 1.6 to obtain  $a|bcy$ .

Since  $a \cdot 1 = a$  we find  $a|a$ , and then by 1.6 we get  $a|acx$ .

Then, by 1.1 we get  $a|(acx + bcy)$ . We can then do some simple algebraic rearrangement to get  $a|(c \cdot (ax + by)) \implies a|(c \cdot 1) \implies a|c$ .  $\square$

**Theorem 1.42.** Let  $a$ ,  $b$ , and  $n$  be integers. If  $a|n$ ,  $b|n$ , and  $(a, b) = 1$ , then  $ab|n$ .

*Proof.* Since  $a|n$  and  $b|n$  we find integers  $k, j$  such that  $ak = n$  and  $bj = n$ . By the transitive property of equality,  $ak = bj$ . Since  $j$  is an integer, we conclude  $b|ak$ . Since  $(a, b) = 1$ , we invoke 1.41 to find  $b|k$ . Thus, we invoke an integer  $d$  such that  $bd = k$ . Substituting this into  $ak = n$ , we find  $abd = n$ , and since  $d$  is an integer we conclude  $ab|n$ .  $\square$

**Theorem 1.43.** Let  $a$ ,  $b$ , and  $n$  be integers. If  $(a, n) = 1$  and  $(b, n) = 1$ , then  $(ab, n) = 1$ .

*Proof.* Invoking 1.38 twice, we find two pairs of integers,  $x_a, y_a, x_b$ , and  $y_b$  such that  $ax_a + ny_a = 1$  and  $bx_b + ny_b = 1$ . We notice then that  $(ax_a + ny_a) \cdot (bx_b + ny_b) = 1 \cdot 1 = 1$ , and we simplify the left-hand side to  $ax_a bx_b + ax_a ny_b + ny_a bx_b + ny_a ny_b = ab(x_a x_b) + n(ax_a y_b + y_a bx_b + ny_a y_b) = 1$ , and then by closure of the integers and 1.39 we find that  $(ab, n) = 1$ .  $\square$

**Question 1.44.** What hypotheses about  $a$ ,  $b$ ,  $c$ , and  $n$  could be added so that  $ac \equiv bc \pmod{n}$ ? State an appropriate theorem and prove it before reading on.

**I know this from Math Seminar.**  $ac \equiv bc \pmod{n}$  implies  $a \equiv b \pmod{n}$  if and only if  $(c, n) = 1$ .

*Proof.* First, we will show that  $ac \equiv bc \pmod{n}$  and  $(c, n) = 1$  imply that  $a \equiv b \pmod{n}$ .

Notice that  $ac \equiv bc \pmod{n}$  implies  $n|(bc - ac)$ . By distribution, we obtain  $n|(c(b - a))$ . Then, since  $(c, n) = 1$ , we cite 1.41 to obtain  $n|(b - a)$ , which by definition means  $a \equiv b \pmod{n}$ .

Now, we will show that if  $(c, n) > 1$ , then  $ac \equiv bc \pmod{n}$  does *not* imply  $a \equiv b \pmod{n}$ .

We will do this by example. Notice that  $n|(c \cdot (n/(c, n)))$ : the right-hand side can be rearranged to read  $n \cdot (c/(c, n))$  and  $c/(c, n)$  is an integer because  $(c, n)$  is a factor of  $c$ . Then, since  $n|n$ , we cite 1.6 to find  $n|(n \cdot (c/(c, n)))$ . We then cite the facts that  $n|0$  and 1.2 to find  $n|((c \cdot (n/(c, n))) - 0)$ , and we can substitute in  $c \cdot 0$  for 0 to find  $n|((c \cdot (n/(c, n))) - c \cdot 0)$ . We then, by definition, obtain  $c \cdot (n/(c, n)) \equiv c \cdot 0 \pmod{n}$ .

However, since  $n > 0$  (because congruence “modulo  $n$ ” is defined) and  $(c, n) > 1$ , we find that  $0 < n/(c, n) < n$ . This implies that  $n/(c, n) \not\equiv 0 \pmod{n}$ , despite the fact that  $c \cdot (n/(c, n)) \equiv c \cdot 0 \pmod{n}$ , giving us our counterexample.  $\square$

**Theorem 1.45.** Let  $a$ ,  $b$ ,  $c$ , and  $n$  be integers with  $n > 0$ . If  $ac \equiv bc \pmod{n}$  and  $(c, n) = 1$ , then  $a \equiv b \pmod{n}$ .

See 1.44.

**Question 1.46.** Suppose  $a$ ,  $b$ , and  $c$  are integers and that there is a solution to the linear Diophantine equation  $ax + by = c$ . That is, suppose there are integer  $x$  and  $y$  that satisfy the equation  $ax + by = c$ . What condition must  $c$  satisfy in terms of  $a$  and  $b$ ?

Since  $(a, b)|(ax + by)$ , we conclude  $(a, b)|c$ .

**Question 1.47.** Can you make a conjecture by completing the following statement?

**Paul’s Conjecture 2.** Given integers  $a$ ,  $b$ , and  $c$ , there exist integers  $x$  and  $y$  that satisfy the equation  $ax + by = c$  if and only if  $(a, b)|c$ .

*Proof.* Notice that an integer solution to  $ax + by = c$  implies that, since  $(a, b)|a$  and  $(a, b)|b \implies (a, b)|(ax + by)$  (1.6 and 1.1), we conclude  $(a, b)|c$ .

Now, notice  $(a, b)|c \implies \exists d \in \mathbb{Z} \ni d(a, b) = c$ . We invoke 1.40 to find integers  $w$  and  $z$  such that  $aw + bz = (a, b)$ . Then, we can multiply both sides by  $d$  to obtain  $d(aw + bz) = d(a, b)$ , which simplifies to  $awd + bzd = c$ , giving us the solution  $x = wd$  and  $y = zd$ .  $\square$

**Theorem 1.48.** Given integers  $a$ ,  $b$ , and  $c$  with  $a$  and  $b$  not both 0, there exist integers  $x$  and  $y$  that satisfy the equation  $ax + by = c$  if and only if  $(a, b)|c$ .

See Paul’s Conjecture 2.

**Question 1.49.** For integers  $a$ ,  $b$ , and  $c$ , consider the linear Diophantine equation  $ax + by = c$ . Suppose integers  $x_0$  and  $y_0$  satisfy the equation: that is,  $ax_0 + by_0 = c$ . What other values

$$x = x_0 + h \text{ and } y = y_0 + k$$

also satisfy  $ax + by = c$ ? Formulate a conjecture that answers this question. Devise some numerical examples to ground your exploration. For example,  $6(-3) + 15 \cdot 2 = 12$ . Can you find other integers  $x$  and  $y$  such that  $6x + 15y = 12$ ? How many other pairs of integers  $x$  and  $y$  can you find? Can you find infinitely many other solutions?

**Paul's Conjecture 3.** The integers  $x_1 = x_0 + h$  and  $y_1 = y_0 + k$  satisfy the equation  $ax_1 + by_1 = c$  if and only if  $\frac{b}{(a,b)}|h$  and  $k = -\frac{ah}{b}$ .

*Proof.* First, notice  $ax_1 + by_1 = c$  if and only if  $a(x_0 + h) + b(y_0 + k) = c$ . Then with rearrangement, we find this is equivalent to  $ax_0 + by_0 + ah + bk = c \iff c + ah + bk = c \iff ah + bk = 0$ . Then, we find  $bk = -ah \iff k = -(ah/b)$ .

Notice that this “if-and-only-if chain” doesn’t show that  $k$  is an integer. Thus, we will show that  $k$  is an integer if and only if  $(b/(a,b))|h$ , the other condition, to complete our proof.

First, notice  $\frac{b}{(a,b)}|h \implies \exists d \in \mathbb{Z} \ni \frac{b}{(a,b)}d = h$ . Then,  $\frac{b}{(a,b)}da = ah$ . This can be rewritten as  $b \cdot (d\frac{a}{(a,b)}) = ah$ , and since  $a/(a,b)$  is an integer we conclude  $b|ah$ . In other words,  $k = -(ah/b)$  is an integer.

Going the opposite direction is much the same:  $k = -(ah/b)$  being an integer implies  $b|ah$ , implying  $bd = ah$ , implying  $bd/(a,b) = ah/(a,b)$ , implying  $\frac{b}{(a,b)}|\frac{ah}{(a,b)}$ . Then, we notice that since there exist integers  $\gamma$  and  $\delta$  such that  $a\gamma + b\delta = (a,b)$  (1.40), we find  $\frac{a}{(a,b)}\gamma + \frac{b}{(a,b)}\delta = \frac{(a,b)}{(a,b)} = 1$ , which by 1.39 implies that  $(\frac{a}{(a,b)}, \frac{b}{(a,b)}) = 1$ . Thus, we cite 1.41 with  $\frac{b}{(a,b)}|\frac{ah}{(a,b)}$  to find  $\frac{b}{(a,b)}|h$ .  $\square$

**Exercise 1.50.** A farmer lays out the sum of 1,770 crowns in purchasing horses and oxen. He pays 31 crowns for each horse and 21 crowns for each ox. What are the possible numbers of horses and oxen that the farmer bought?

51 horses and 9 oxen is the first situation I found. Using Paul’s Conjecture 3, we can find that further solutions can be found by subtracting 21 from the number of horses while adding 31 to the number of oxen (trust me it makes sense).

30 horses and 40 oxen.

9 horses and 71 oxen.

**Theorem 1.51.** Let  $a$ ,  $b$ ,  $c$ ,  $x_0$ , and  $y_0$  be integers with  $a$  and  $b$  not both 0 such that  $ax_0 + by_0 = c$ . Then the integers

$$x = x_0 + \frac{b}{(a,b)} \text{ and } y = y_0 - \frac{a}{(a,b)}$$

also satisfy the linear Diophantine equation  $ax + by = c$ .

*Proof.* Notice these integers satisfy the requirements for Paul’s Conjecture 3 (I’m too lazy to show how but 1.53 will force me to).  $\square$

**Question 1.52.** If  $a$ ,  $b$ , and  $c$  are integers with  $a$  and  $b$  not both 0, and the linear diophantine equation  $ax + by = c$  has at least one integer solution, can you find a general expression for all the integer solutions to that equation? Prove your conjecture.

**Paul's Conjecture 4.** The set of all pairs of integers  $(x_1, y_1)$  such that  $ax_1 + by_1 = c$  can be written as

$$\left\{ \left( x_0 + \frac{bd}{(a,b)}, y_0 - \frac{ad}{(a,b)} \right) \mid d \in \mathbb{Z} \right\}$$

*Proof.* Paul’s Conjecture 3 can easily be extended here: if we let the integer solution given be  $x_0$  and  $y_0$ , such that  $ax_0 + by_0 = c$ , we want to find a general expression for all integers  $x_1 = x_0 + h$  and  $y_1 = y_0 + k$  where  $\frac{b}{(a,b)}|h$  and  $k = -\frac{ah}{b}$ .

The set of all integers  $h$  such that  $\frac{b}{(a,b)}|h$  can be expressed as  $\{ \frac{bd}{(a,b)} \mid d \in \mathbb{Z} \}$ . The corresponding  $k$  value for any  $h$  is  $-\frac{ah}{b} = -\frac{a(bd/(a,b))}{b} = -\frac{ad}{(a,b)}$ . Thus, any pair of  $x_1 = x_0 + \frac{bd}{(a,b)}$  and  $y_1 = y_0 - \frac{ad}{(a,b)}$  satisfies the Diophantine equation  $ax_1 + by_1 = c$ .  $\square$

**Theorem 1.53.** Let  $a$ ,  $b$ , and  $c$  be integers with  $a$  and  $b$  not both 0. If  $x = x_0$ ,  $y = y_0$  is an integer solution to the equation  $ax + by = c$  (that is,  $ax_0 + by_0 = c$ ) then for every integer  $k$ , the numbers

$$x = x_0 + \frac{kb}{(a,b)} \text{ and } y = y_0 - \frac{ka}{(a,b)}$$

are integers that also satisfy the linear Diophantine equation  $ax + by = c$ . Moreover, every solution to the linear Diophantine equation  $ax + by = c$  is of this form.

*Proof.* This is just a less pretentious way of saying Paul's Conjecture 4 that doesn't involve set notation.  $\square$

**Exercise 1.54.** Find all integer solutions to the equation  $24x + 9y = 33$ .

$$(x, y) \in \{(1 + 3k, 1 - 8k) \mid k \in \mathbb{Z}\}.$$

**Theorem 1.55.** If  $a$  and  $b$  are integers, not both 0, and  $k$  is a natural number, then  $\gcd(ka, kb) = k \cdot \gcd(a, b)$ .

*Proof.* First, we notice that  $k \cdot (a, b)$  is indeed a common factor of  $ka$  and  $kb$ , since  $(a, b) \mid a$  we conclude  $k(a, b) \mid ka$ , and similarly for  $k(a, b) \mid kb$ .

Now, we invoke 1.40 to find integers  $x$  and  $y$  such that  $ax + by = (a, b)$ . We can multiply both sides by  $k$  to find  $k(ax + by) = kax + kby = k(a, b)$ , and then from that invoke 1.48 with  $ka$  and  $kb$  to find that  $(ka, kb) \mid k(a, b)$ . Since  $(ka, kb)$  is the greatest common factor of  $ka$  and  $kb$ , and  $k(a, b)$  is a common factor of  $ka$  and  $kb$ , we conclude  $k(a, b) \leq (ka, kb)$ . However, since  $k(a, b)$  is positive and  $(ka, kb) \mid k(a, b)$ , we conclude  $k(a, b) \geq (ka, kb)$ . Thus, we conclude  $k(a, b) = (ka, kb)$ .  $\square$

**Exercise 1.56.** For natural numbers  $a$  and  $b$ , give a suitable definition for "least common multiple of  $a$  and  $b$ ," denoted  $\text{lcm}(a, b)$ . Construct and compute some examples.

Define  $\text{lcm}(a, b)$  as the smallest positive number  $x$  such that  $a \mid x$  and  $b \mid x$ .

Some examples include  $\text{lcm}(3, 6) = 6$ ,  $\text{lcm}(1, 50) = 50$ , and  $\text{lcm}(2, 5) = 10$ .

**Theorem 1.57.** If  $a$  and  $b$  are natural numbers, then  $\gcd(a, b) \cdot \text{lcm}(a, b) = ab$ .

*Proof.* Notice by 1.55 that  $\gcd(a, b) \cdot \text{lcm}(a, b) = \gcd(a \text{ lcm}(a, b), b \text{ lcm}(a, b))$ .

Since  $a \mid \text{lcm}(a, b)$  we can write  $\text{lcm}(a, b) = ak$  for some integer  $k$ . Similarly, we can write  $\text{lcm}(a, b) = bj$  for an integer  $j$ . Then, we simplify our expression to  $\gcd(a \text{ lcm}(a, b), b \text{ lcm}(a, b)) = \gcd(abj, bak)$ . Then, citing 1.55 again, we find this equal to  $ab \gcd(j, k)$ .

Notice that since  $\gcd(j, k) \mid j$ , we can write  $j = x \gcd(j, k)$ , and likewise we can write  $k = y \gcd(j, k)$ . Then, we notice  $ak = bj \implies ay \gcd(j, k) = bx \gcd(j, k)$ . Since  $ay = bx$  is a common multiple of  $a$  and  $b$ , and  $ay \gcd(j, k)$  is the least common multiple of  $a$  and  $b$ , we find  $ay \gcd(j, k) \leq ay$ , which implies  $\gcd(j, k) = 1$ .

Putting this all together, we find  $\gcd(a, b) \cdot \text{lcm}(a, b) = ab \gcd(j, k) = ab$ .  $\square$

**Corollary 1.58.** If  $a$  and  $b$  are natural numbers, then  $\text{lcm}(a, b) = ab$  if and only if  $a$  and  $b$  are relatively prime.

*Proof.* By 1.57, we find  $ab = \text{lcm}(a, b) \cdot \gcd(a, b) \implies \text{lcm}(a, b) = \frac{ab}{\gcd(a, b)}$ . Thus,  $a$  and  $b$  are relatively prime if and only if  $\gcd(a, b) = 1 \iff \text{lcm}(a, b) = \frac{ab}{\gcd(a, b)} = ab$ .  $\square$

## 2 Chapter 2

### Fundamental Theorem of Arithmetic

**Theorem 2.1.** *If  $n$  is a natural number greater than 1, then there exists a prime  $p$  such that  $p|n$ .*

*Proof.* Let  $S = \{k \in \mathbb{Z} \mid k > 1, k|n\}$ . By the Well-Ordering Principle,  $S$  has a smallest element, call it  $s$ . Notice that if  $s = a \cdot b$  (where  $a$  and  $b$  are natural numbers), then  $a, b \leq s$ ,  $a|n$ , and  $b|n$ . Since  $s$  is the smallest number besides 1 that divides  $n$ , we conclude  $a$  and  $b$  cannot both be less than  $s$  (since if either is 1, the other must be  $s$ ). Thus,  $s$  is a prime number such that  $s|n$ .  $\square$

**Exercise 2.2.** *Write down the primes less than 100 without the aid of a calculator or a table of primes and think about how you decide whether each number you select is prime or not.*

2, 3, 5, 7, 11, 13, 17, 19, 23, 29, 31, 37, 41, 43, 47, 53, 59, 61, 67, 71, 73, 79, 83, 89, 97.

**Theorem 2.3.** *A natural number  $n > 1$  is prime if and only if for all primes  $p \leq \sqrt{n}$ ,  $p$  does not divide  $n$ .*

*Proof.* We can easily see that if there is a prime  $p$  such that  $p \leq \sqrt{n}$  and  $p|n$ , then  $n$  is not prime (since  $p \leq \sqrt{n} < n$  and  $pk = n$  for some natural  $k$ ).

Thus, we must show that if for all primes  $p \leq \sqrt{n}$ ,  $p$  does not divide  $n$ , then  $n$  is prime. To do this we will assume  $n$  is composite and show that there must be a prime  $p \leq \sqrt{n}$  that *does* divide  $n$ .

Since  $n$  is composite, we can write  $n = ab$ , where  $a$  and  $b$  are natural numbers both less than  $n$ . Since they are both less than  $n$ , neither can be 1 (or else  $ab < n$ , a contradiction). We also know that one must be less than or equal to  $\sqrt{n}$  (if both  $a$  and  $b$  are greater than  $\sqrt{n}$ , then  $ab > \sqrt{n} \cdot \sqrt{n} = n$  which is a contradiction). Without loss of generality, assume that  $a$  is one guaranteed such that  $1 < a \leq \sqrt{n}$ .

Since  $a > 1$ , by 2.1 we find there exists a prime  $p|a$ , and since  $p \leq a \leq \sqrt{n}$  and  $p|a$  while  $a|n$ , that means we've found a prime  $p \leq \sqrt{n}$  such that  $p|n$ .

Thus, if  $n$  is composite there exists a prime  $p \leq \sqrt{n}$  such that  $p|n$ , which lets us conclude the contrapositive that if there is no such  $p \leq \sqrt{n}$  such that  $p|n$ ,  $n$  must be prime.  $\square$

**Exercise 2.4.** *Use the preceding theorem to verify that 101 is prime.*

The only primes less than or equal to  $\sqrt{101}$  are 2, 3, 5, and 7, none of which divide 101. Thus, 101 is prime.

**Exercise 2.5.** *Do the sieve of eratosthenes. Why are the circled numbers all of the primes less than 100?*

I did this for 2.2. In order for a number  $n$  to be circled, it can't be a multiple of any other prime number  $p$  such that  $p < n$ . By 2.3, this implies  $n$  is prime. (Notice this only works because we start at 2, the first prime, which means the second circle is prime, so the third circle is prime, etc.)

**Exercise 2.6.** *For each natural number  $n$ , define  $\pi(n)$  to be the number of primes less than or equal to  $n$ . Make a guess about approximately how large  $\pi(n)$  is relative to  $n$ . In particular, do you suspect that  $\frac{\pi(n)}{n}$  is generally an increasing or decreasing function? Do you suspect that it approaches some specific limit as  $n \rightarrow \infty$ ? etc. etc.*

Man  $\frac{\pi(n)}{n}$  sure seems to, uh, go down. Some python I wrote indicates that it (VERY slowly) works its way down, the lowest I've seen is about 0.12. Maybe it converges to something nice like .1, although I doubt it and suspect it works down to 0.

**Theorem 2.7.** *Every natural number greater than 1 is either a prime number or it can be expressed as a finite product of prime numbers. That is, for every natural number  $n$  greater than 1, there exist distinct primes  $p_1, p_2, \dots, p_m$  and natural numbers  $r_1, r_2, \dots, r_m$  such that*

$$n = p_1^{r_1} p_2^{r_2} \cdots p_m^{r_m}.$$

*Proof.* Since  $n > 1$ , it is either prime or composite. If  $n$  is prime, we're done. If not, let  $j$  and  $k$  be the natural numbers greater than 1 such that  $n = jk$ .

Since  $j$  and  $k$  are natural numbers greater than 1, they are either prime or composite. If they're both prime, we're done. In the other case, let's assume without loss of generality that  $j$  is composite and  $k$  is prime. Then, we can split  $j$  into natural numbers greater than 1, call them  $a$  and  $b$  so that  $j = ab$ . Then,  $n = abk$ .

Now,  $a$  and  $b$  must either be prime or composite. If they are both prime, we're done. If not, ... etc. etc.

Notice that since  $j, k < n$  and  $a, b < j$ , etc. etc., the numbers we're working with get smaller with every step. Since these numbers must also be natural numbers, they can't get smaller *forever*: in other words, this process must cease at some point (if it didn't, it would imply there are infinitely many natural numbers that are less than  $n$ , which is absurd). When this process terminates, we'll find that  $n$  is a product of primes.  $\square$

**Theorem 2.8.** Let  $p$  and  $q_1, q_2, \dots, q_n$  all be primes and let  $k$  be a natural number such that  $pk = q_1 q_2 \cdots q_n$ . Then  $p = q_i$  for some  $i$ .

*Proof.* We will do a proof by contradicition (!!). Assume that  $p \neq q_i$  for any  $i$ .

Take any  $q_i$ . The divisors of  $p$  are 1 and  $p$ , and the divisors of  $q_i$  are 1 and  $q_i$ , since both are prime. Since we know  $p \neq q_i$ , we find that  $(p, q_i) = 1$ . Thus, by 1.41, since we know  $p | (q_1 \cdots q_n)$ , we find  $p | (q_1 \cdots q_{i-1} \cdot q_{i+1} \cdots q_n)$ .

We can use this process to “remove” each  $q_i$  term from the multiplaction, finding that  $p | 1$ . Since  $p$  is a prime, we know  $p > 1$ , giving us a contradicition. Thus, our assumption is false, and there exist a  $q_i$  such that  $p = q_i$ .  $\square$

**Theorem 2.9.** Let  $n$  be a natural number. Let  $P = \{p_1, p_2, \dots, p_m\}$  and  $Q = \{q_1, q_2, \dots, q_s\}$  be sets of primes with  $p_1 \neq p_j$  if  $i \neq j$  and  $q_i \neq q_j$  if  $i \neq j$ . Let  $\{r_1, r_2, \dots, r_m\}$  and  $\{t_1, t_2, \dots, t_s\}$  be sets of natural numbers such that

$$\begin{aligned} n &= p_1^{r_1} p_2^{r_2} \cdots p_m^{r_m} \\ &= q_1^{t_1} q_2^{t_2} \cdots q_s^{t_s} \end{aligned}$$

Then  $m = s$  and  $\{p_1, p_2, \dots, p_m\} = \{q_1, q_2, \dots, q_s\}$ . That is, the sets of primes are equal but their elements are not necessarily listed in the same order; that is,  $p_i$  may or may not equal  $q_i$ . Moreover, if  $p_i = q_j$  then  $r_i = t_j$ . In other words, if we express the same natural number as a product of powers of distinct primes, then the expressions are identical except for the ordering of the factors.

*Proof.* We will start with the proof that  $P = Q$ , by double inclusion.

Take  $p \in P$ . It's clear  $p | n$  (since  $p$  is a part of a product that equals  $n$ ), and thus that  $p | (q_1^{t_1} \cdots q_s^{t_s})$ . We can then use a similar logic that we used in the proof of 2.8: if  $p \notin Q$ , then for all  $q_i$  we find that  $(p, q_i) = 1$ , and using this by 1.41 we can slowly remove terms from the product on the right until we eventually reach  $p | 1$ , which is absurd, implying that the assumption  $p \notin Q$  is false. Thus,  $\forall p \in P, p \in Q$ , or in other words  $P \subset Q$ .

Take the bit above and swap around the letters and you find  $Q \subset P$ , completing our double inclusion proof that  $P = Q$ .

Our logic that  $p_i = q_j$  implies  $r_i = t_j$  will feel very similar.

Since  $n = m$ , we know that  $p_1^{r_1} \cdots p_m^{r_m} = q_1^{t_1} \cdots q_m^{t_m}$  (since  $P = Q$  we know  $|P| = |Q|$  and thust  $m = s$ ).

Notice this means  $p_i^{r_i} | (q_1^{t_1} \cdots q_m^{t_m})$ . As above, we continually cite 1.41 to remove terms from the right hand side.

We can do this even when raising  $p_i$  to a power because, as per the first half of this proof, any prime factorizaion of  $p_i^{r_i}$  will contain only the same primes as the factorization “ $p_i^{r_i}$ ,” and thus will only contain  $p_i$ . In other words, it's impossible to create a product that is equal to  $p_i^{r_i}$  using any other primes, and thus no other prime divides  $p_i^{r_i}$  so it cannot have any common factors with other prime numbers.

Notice, however, that  $(p_i^{r_i}, q_j) = q_j = p_i$ , so we cannot remove those terms, leaving us with  $p_i^{r_i} | q_j^{t_j}$ . This lets us conclude that (since both numbers are positive)  $p_i^{r_i} \leq q_j^{t_j}$ , which implies  $r_i \leq t_j$ .

Now, as above, we take the logic above and swap all of the letters to conclude that  $q_j^{t_j} | p_i^{r_i}$ , and thus that  $q_j^{t_j} \leq p_i^{r_i}$  and finally that  $t_j \leq r_i$ .

Since  $t_j \leq r_i \leq t_j$ , we conclude  $r_i = t_j$ , completing our proof that  $p_i = q_j$  implies  $r_i = t_j$ .  $\square$

**Exercise 2.10.** Express  $n = 12!$  as a product of primes.

$$\begin{aligned} 12! &= 12 \cdot 11 \cdot 10 \cdot 9 \cdot 8 \cdot 7 \cdot 6 \cdot 5 \cdot 4 \cdot 3 \cdot 2 \cdot 1 \\ &= (2^2 \cdot 3) \cdot 11 \cdot (2 \cdot 5) \cdot (3^2) \cdot (2^3) \cdot 7 \cdot (2 \cdot 3) \cdot 5 \cdot (2^2) \cdot 3 \cdot 2 \\ &= 2^{10} \cdot 3^5 \cdot 5^2 \cdot 7 \cdot 11 \end{aligned}$$

**Exercise 2.11.** Determine the number of zeroes at the end of  $25!$

In which base?

In base 10 what this is really asking is how many 2s and 5s divide  $25!$ . I promise you on my life that 2s are not going to be the limiting factor here, so we can focus on how high of a power of 5 divides  $25!$ .

We get one 5 from 5, 10, 15, and 20. We get two from 25. That gives us  $5^6 | 25!$ , so there are 6 zeroes on the end of  $25!$ .

(As promised,  $2^{23} | 25!$ , so 2 is not even remotely close to limiting the number of 0s).

## Applications of the Fundamental Theorem of Arithmetic

**Theorem 2.12.** Let  $a$  and  $b$  be natural numbers greater than 1 and let  $p_1^{r_1} p_2^{r_2} \cdots p_m^{r_m}$  be the unique prime factorization of  $a$  and let  $q_1^{t_1} q_2^{t_2} \cdots q_s^{t_s}$  be the unique prime factorization of  $b$ . Then  $a|b$  if and only if for all  $i \leq m$  there exists a  $j \leq s$  such that  $p_i = q_j$  and  $r_i \leq t_j$ .

*Proof.* Woo boy. Let's start by showing  $a|b$  implies... all of that.

We know that  $a|b$  means  $ak = b$ . This means that  $p_1^{r_1} \cdots p_m^{r_m} k = q_1^{t_1} \cdots q_s^{t_s}$ . Since  $k$  is an integer (and a natural number, given both  $a$  and  $b$  are natural) we know that it has its own unique prime factorization. Thus, the prime factorization of  $a$  times the prime factorization of  $k$  must be equal to the prime factorization of  $b$  (since  $ak = b$  and prime factorizations are unique).

When we multiply the prime factorization of  $a$  by that of  $k$ , we cannot remove any of the terms  $p_1 \cdots p_m$ , nor can we reduce any of the exponents  $r_1 \cdots r_m$ , since the prime factorization of  $k$  will not contain the multiplicative inverse of any prime. Thus, in order for our product to be the prime factorization of  $b$ , all of the primes  $p_1 \cdots p_m$  must also be included in the prime factorization of  $b$ , and all of the exponents  $r_1 \cdots r_m$  must be less than or equal to the corresponding exponents in the prime factorization of  $b$ .

Now the other direction. If we know that for all  $i \leq m$  there exists a  $j \leq s$  such that  $p_i = q_j$  and  $r_i \leq t_j$ , then we can rewrite  $b$  as  $(p_1^{r_1} \cdots p_m^{r_m}) \cdot (q_1^{t'_1} \cdots q_s^{t'_s})$ , where  $t'_1 \cdots t'_s$  are the exponents on the relative prime modified to accommodate "moving"  $p_1^{r_1}$  through  $p_m^{r_m}$  to the front of the product (these exponents notably may be 0). Since  $q_1^{t'_1} \cdots q_s^{t'_s}$  is an integer (call it  $k$ ) and  $p_1^{r_1} \cdots p_m^{r_m}$ , we've shown that  $b = ak$ , or in other words  $a|b$ .  $\square$

**Theorem 2.13.** If  $a$  and  $b$  are natural numbers and  $a^2|b^2$ , then  $a|b$ .

*Proof.* Let  $a = p_1^{r_1} \cdots p_m^{r_m}$  and  $b = q_1^{t_1} \cdots q_s^{t_s}$  be the unique prime factorizations of these numbers.

Notice that  $a^2 = p_1^{2r_1} \cdots p_m^{2r_m}$  and  $b^2 = q_1^{2t_1} \cdots q_s^{2t_s}$ , and that these are the prime factorizations of these numbers.

By 2.12, we find  $a^2|b^2$  implies that for all  $i \leq m$  there exists a  $j \leq s$  such that  $p_i = q_j$  and  $2r_i \leq 2t_j$ . This implies that  $r_i \leq t_j$ , so we conclude that for all  $i \leq m$  there exists a  $j \leq s$  such that  $p_i = q_j$  and  $r_i \leq t_j$ . By 2.12, this means  $a|b$ .  $\square$

**Exercise 2.14.** Find  $(3^1 4 \cdot 7^2 2 \cdot 11^5 \cdot 17^3, 5^2 \cdot 11^4 \cdot 13^8 \cdot 17)$

$$11^4 \cdot 17$$

**Exercise 2.15.** Find  $\text{lcm}(3^1 4 \cdot 7^2 2 \cdot 11^5 \cdot 17^3, 5^2 \cdot 11^4 \cdot 13^8 \cdot 17)$

$$3^1 4 \cdot 5^2 \cdot 7^2 2 \cdot 11^5 \cdot 13^8 \cdot 17^3$$

**Exercise 2.16.** Make a conjecture that generalizes the ideas you used to solve the two previous exercises.

**Paul's Conjecture 5.** Let the primes be denoted  $p_i$ , where  $p_1 = 2$ ,  $p_2 = 3$ ,  $p_3 = 5$ ,  $p_4 = 7$ ,  $p_5 = 11$ , etc.

Let  $a = p_1^{r_1} p_2^{r_2} \cdots$  and  $b = p_1^{t_1} p_2^{t_2} \cdots$  be the prime factorizations of natural numbers  $a$  and  $b$ , where  $r_i$  and  $t_j$  can be 0 to indicate the absence of a prime. Then

$$\gcd(a, b) = p_1^{\min(r_1, t_1)} p_2^{\min(r_2, t_2)} \cdots = \prod_{i \in \mathbb{N}} p_i^{\min(r_i, t_i)} \quad \text{and}$$

$$\text{lcm}(a, b) = p_1^{\max(r_1, t_1)} p_2^{\max(r_2, t_2)} \cdots = \prod_{i \in \mathbb{N}} p_i^{\max(r_i, t_i)}.$$

**Question 2.17.** Do you think this method is always better, always worse, or sometimes better and sometimes worse than using the Euclidean Algorithm to find  $(a, b)$ ? Why?

For large numbers, for humans, this method is probably better because you can use divisibility rules to easily start prime factorizing the number and make it smaller and easier to work with (although, for numbers that are the products of only large primes like  $29 \cdot 31$  or something this might be painful).

For computers the Euclidean Algorithm is almost certainly better, because you can easily find the quotient/remainder through repeated addition and it's very fast.

**Theorem 2.18.** *Given  $n + 1$  natural numbers, say  $a_1, a_2, \dots, a_{n+1}$ , all less than or equal to  $2n$ , then there exists a pair, say  $a_i$  and  $a_j$  with  $i \neq j$ , such that  $a_i | a_j$ .*

*Proof.* Credit to Sam.

We'll use the pigeonhole principle. We'll form sets  $S_1$  through  $S_{2n-1}$  for all odd indices, with each set  $S_t = \{t \cdot 2^n \mid n \in \mathbb{N} \cup \{0\}\}$ .

Notice that if any two of our numbers  $a_i$  and  $a_j$  fall into the same  $S_t$ , then  $a_i = t \cdot 2^n$  and  $a_j = t \cdot 2^m$ . Assuming WLOG that  $n \leq m$ , we find  $a_j = a_i \cdot 2^{m-n}$ , which since  $2^{m-n}$  is an integer (as  $m - n \geq 0$ ) shows  $a_i | a_j$ . Thus, we only need show that two of our  $a$ 's fall into the same set.

Notice then that every  $a_i$  will fall into at least (in fact, exactly) one  $S_t$ . Take  $a_i$ 's prime factorization, let it be  $p_1^{r_1} \cdots p_m^{r_m}$ .

Then if  $2 \neq p_v$  for any  $v \leq n$ , since  $a_i$  is odd we find  $a_i = a_i \cdot 2^0$  and thus  $a_i \in S_{a_i}$ .

If  $2 = p_v$  for some  $v \leq n$ , then we notice  $a_i = 2^{r_v} \cdot (p_1^{r_1} \cdots p_{v-1}^{r_{v-1}} p_{v+1}^{r_{v+1}} \cdots p_m^{r_m})$ . Let's define that second term as  $k$ . Since all of the  $p$ 's are unique, we know that  $k$  is odd, and thus  $a_i = S_k$ .

Since there are only sets  $S$  for each of the odd numbers between 1 and  $2n$ , there are exactly  $n$  sets. Since there are  $n + 1$  numbers in our set of  $a$ 's, by the pigeonhole principle, we know there must be  $a_i, a_j$  such that  $i \neq j$ ,  $a_i \in S_t$ , and  $a_j \in S_t$  for some  $t$ . As we showed earlier, this implies that either  $a_i | a_j$  or vice versa, completing our proof.  $\square$

**Theorem 2.19.** *There do not exist natural numbers  $m$  and  $n$  such that  $7m^2 = n^2$ .*

*Proof.* In the prime factorization of  $n^2$  the exponent on 7 must be even, as it is double the exponent on 7 in the prime factorization of  $n$ .

In the prime factorization of  $7m^2$ , the exponent on 7 must be odd, as it is double the exponent on 7 in the prime factorization of  $m$  plus one (for multiplying by 7).

Since prime factorizations are unique,  $7m^2$  and  $n^2$  having different exponents (for the same number cannot be both even and odd) implies they are different numbers and thus not equal.  $\square$

**Theorem 2.20.** *There do not exist natural numbers  $m$  and  $n$  such that  $24m^3 = n^3$ .*

*Proof.* Notice  $24m^3 = 2^3 \cdot 3 \cdot m^3$ .

Then, apply the logic above to the exponent on 3 in the prime factorization of these two numbers; it must be a multiple of 3 in  $n^3$ , and yet it must be one more than a multiple of 3 in  $24m^3 = 2^3 \cdot 3 \cdot m^3$ . Since the same number cannot be both (as  $0 \not\equiv 1 \pmod{3}$ ), the prime factorizations of  $n^3$  and  $24m^3$  are not the same and thus the numbers cannot be equal.  $\square$

**Exercise 2.21.** *Show that  $\sqrt{7}$  is irrational. That is, there do not exist natural numbers  $n$  and  $m$  such that  $\sqrt{7} = \frac{n}{m}$ .*

*Proof.* If there were such numbers  $n$  and  $m$ , then we would find  $\sqrt{7} \cdot m = n$ , implying  $7m^2 = n^2$ , a contradiction with 2.19. Thus, no such numbers exist.  $\square$

**Exercise 2.22.** *Show that  $\sqrt{12}$  is irrational.*

If  $\sqrt{12} = \frac{a}{b}$  for integers  $a, b$ , then  $12b^2 = a^2$ , which is impossible due to the same logic we used in 2.20.

**Exercise 2.23.** *Show that  $7^{\frac{1}{3}}$  is irrational.*

If  $7^{\frac{1}{3}} = \frac{a}{b}$ , then  $7b^3 = a^3$ . This is impossible for integers  $a$  and  $b$ , as the prime factorization of  $7b^3$  has an exponent on 7 that is one greater than a multiple of 3, while the prime factorization of  $a^3$  has an exponent on 7 that is a multiple of 3.

**Question 2.24.** *What other numbers can you show to be irrational? Make and prove the most general conjecture you can.*

**Paul's Conjecture 6.** *Let  $w$  be an integer, with  $w = p_1^{r_1} \cdot p_2^{r_2} \cdots p_t^{r_t}$  its prime factorization.  $w^{\frac{n}{m}}$  (where  $n$  and  $m$  are integers) is irrational if for any one prime  $p_i$  with  $1 \leq i \leq t$  it is the case that  $m \nmid (n \cdot r_i)$ .*

*Proof.* Say it is the case there exists a  $p_i$  such that  $m \nmid (n \cdot r_i)$ . We then find  $p_i^{r_i} | w$ , so let's invoke  $k$  such that  $w = kp_i^{r_i}$ . Notice  $p_i \nmid k$  due to the fact that  $k = \frac{w}{p_i^{r_i}}$  which has no  $p_i$ 's in its prime factorization. We then find  $w^{\frac{n}{m}} = k^{\frac{n}{m}} \cdot p_i^{\frac{nr_i}{m}}$ .

Say  $w^{\frac{n}{m}} = k^{\frac{n}{m}} \cdot p_i^{\frac{nr_i}{m}} = \frac{a}{b}$ . To show  $w^{\frac{n}{m}}$  is irrational, we will assume  $a$  and  $b$  are both integers and rearrange the equation, we find  $k^{\frac{n}{m}} \cdot p_i^{\frac{nr_i}{m}} \cdot b = a$ , and then raising both sides to the  $m$ th power we find  $k^n \cdot p_i^{nr_i} \cdot b^m = a^m$ . Now

both sides of this equation are integers, which means we can compare their prime factorizations. Specifically, we are going to look at the exponent on  $p_i$  in these prime factorizations.  $k$  has no impact on this exponent (since  $p_i \nmid k$ ).  $b^m$  provides some multiple of  $m$  to this exponent, while  $p_i$  provides  $nr_i$ ; in other words, the exponent on  $p_i$  on the left side is of the form  $\alpha m + nr_i$  for some integer  $\alpha$ . On the left, since we only have  $a^m$ , we have an exponent of the form  $\beta m$  for some integer  $\beta$ . Since these two are equal, we find  $\alpha m + nr_i = \beta m$ , which tells us  $m | (\alpha m + nr_i)$ , which then since  $m | \alpha m$  we cite 1.2 to find  $m | nr_i$ , a contradiction.

Thus,  $a$  and  $b$  cannot both be integers, and thus  $w^{\frac{n}{m}}$  is irrational.  $\square$

**Theorem 2.25.** *Let  $a$ ,  $b$ , and  $n$  be integers. If  $a|n$ ,  $b|n$ , and  $(a, b) = 1$ , then  $ab|n$ .*

*Proof.* Let  $n = p_1^{r_1} \cdots p_m^{r_m}$  be the prime factorization of  $n$ . Then, by 2.12, we can write  $a = p_1^{\alpha_1} \cdots p_m^{\alpha_m}$  and  $b = p_1^{\beta_1} \cdots p_m^{\beta_m}$ , where for all  $i$  with  $1 \leq i \leq m$  we know  $0 \leq \alpha_i, \beta_i \leq r_i$ .

Say  $ab \nmid n$ . Since  $ab = p_1^{\alpha_1 + \beta_1} \cdots p_m^{\alpha_m + \beta_m}$ , we invoke 2.12 to find there must be some  $j$  such that  $1 \leq j \leq m$  and  $\alpha_j + \beta_j > r_j$  (since all of the primes in the prime factorization of  $ab$  are represented in  $p_1$  through  $p_m$ ). However, since  $\alpha_j \leq r_j$ , this implies  $\beta_j \geq 1$ , and similarly that  $\alpha_j \geq 1$ . This means that since  $p_j^{\alpha_j} | a$ , we know  $p_j | a$ , and similarly that  $p_j | b$  making  $p_j$  a common divisor of  $a$  and  $b$ . Since  $p_j$  is prime,  $p_j > 1$ , and since  $(a, b) = 1$ , we find that  $p_j$  is a common divisor of  $a$  and  $b$  greater than their greatest common divisor, a contradiction. Thus, our assumption that  $ab \nmid n$  is false, and we find  $ab|n$ .  $\square$

**Theorem 2.26.** *Let  $p$  be a prime and let  $a$  be an integer. Then  $p$  does not divide  $a$  if and only if  $(a, p) = 1$ .*

*Proof.* That  $p$  does not divide  $a$  if  $(a, p) = 1$  is trivial, since if it did it would be a common divisor (as  $p|p$ ) that is greater than 1 (since  $p$  is prime) which is impossible since  $(a, p) = 1$ .

All that is left is to show that  $p \nmid a$  implies that  $(a, p) = 1$ . Since  $p$  is prime, its only (natural) divisors are 1 and  $p$ . Thus, these are the only candidates for  $(a, p)$ . Since  $p \nmid a$ , though,  $p$  is not a common divisor, and thus the only possibility for  $(a, p)$  is 1.  $\square$

**Theorem 2.27.** *Let  $p$  be a prime and let  $a$  and  $b$  be integers. If  $p|ab$ , then  $p|a$  or  $p|b$ .*

*Proof.* By 2.12, we know  $p$  has to show up in the prime factorization of  $ab$ . Since the prime factorization of  $ab$  only includes primes found in either the factorization of either  $a$  or  $b$  (as it can be obtained by replacing  $a$  and  $b$  with their prime factorizations and moving the terms around), this means  $p$  must show up in the prime factorization of  $a$  or  $b$ , and thus by 2.12 either  $p|a$  or  $p|b$ .  $\square$

**Theorem 2.28.** *Let  $a$ ,  $b$ , and  $c$  be integers. If  $(b, c) = 1$ , then  $(a, bc) = (a, b) \cdot (a, c)$ .*

*Proof.* We invoke 1.40 twice to find integers  $x_1, x_2, y_1, y_2$  such that  $ax_1 + bx_2 = (a, b)$  and  $ay_1 + cy_2 = (a, c)$ . Then, we multiply the two equations together to get  $(ax_1 + bx_2) \cdot (ay_1 + cy_2) = (a, b) \cdot (a, c)$ . With some rearrangement we find  $a^2x_1y_1 + abx_2y_1 + acx_1y_2 + bcx_2y_2 = (a, b) \cdot (a, c)$ , which with distributivity we find means  $a(ax_1y_1 + bx_2y_1 + cx_1y_2) + bc(x_2y_2) = (a, b) \cdot (a, c)$ . Since  $ax_1y_1 + bx_2y_1 + cx_1y_2$  and  $x_2y_2$  are integers, we invoke 1.48 to find  $(a, bc) | ((a, b) \cdot (a, c))$ . Thus,  $(a, bc) \leq (a, b) \cdot (a, c)$ .

We know that  $(a, b) | a$  and that  $(a, c) | a$ . We also know that  $((a, b), (a, c)) = 1$  (if it didn't, it would be a common factor of  $b$  and  $c$  greater than 1 which is impossible). Thus, we cite 1.42 to find  $((a, b) \cdot (a, c)) | a$ . Thus, since it is a common factor, it is less than the greatest common factor, so we conclude  $(a, b) \cdot (a, c) \leq (a, bc)$ .

Thus we have  $(a, bc) \leq (a, b) \cdot (a, c) \leq (a, bc)$ , so we conclude  $(a, bc) = (a, b) \cdot (a, c)$ .  $\square$

**Theorem 2.29.** *Let  $a$ ,  $b$ , and  $c$  be integers. If  $(a, b) = 1$  and  $(a, c) = 1$ , then  $(a, bc) = 1$*

*Proof.* This is just 1.43.  $\square$

**Theorem 2.30.** *Let  $a$  and  $b$  be integers. If  $(a, b) = d$ , then  $(\frac{a}{d}, \frac{b}{d}) = 1$ .*

*Proof.* By 1.40, we know there are integers  $x, y$  such that  $ax + by = d$ . We can then divide both sides by  $d$  to find  $\frac{a}{d}x + \frac{b}{d}y = 1$ . By 1.39, we conclude  $(\frac{a}{d}, \frac{b}{d}) = 1$ .  $\square$

**Theorem 2.31.** *Let  $a$ ,  $b$ ,  $u$ , and  $v$  be integers. If  $(a, b) = 1$  and  $u|a$  and  $v|b$ , then  $(u, v) = 1$ .*

*Proof.* Notice that Since  $(u, v) | u$  and  $u|a$ , we know  $(u, v) | a$ . Similarly, we know  $(u, v) | b$ . Thus, since  $(u, v)$  is a common factor of  $a$  and  $b$ , we know  $(u, v) \leq (a, b) = 1$ . However, since 1 is a common factor of  $u$  and  $v$ , we also know  $(u, v) \geq 1$ . Thus,  $1 \leq (u, v) \leq 1$ , which implies  $(u, v) = 1$ .  $\square$

## The infinitude of primes

**Theorem 2.32.** For all natural numbers  $n$ ,  $(n, n+1) = 1$ .

*Proof.* Since 1 is a common factor of  $n$  and  $n+1$ , we know  $(n, n+1) \geq 1$ .

Since  $(n, n+1) | n$  and  $(n, n+1) | n+1$ , we know by 1.2 that  $(n, n+1) | ((n+1) - n)$ , or in other words  $(n, n+1) | 1$ . Since  $(n, n+1)$  is natural, we know  $(n, n+1) \leq 1$ .

Thus, we know  $1 \leq (n, n+1) \leq 1$ , and thus we conclude  $(n, n+1) = 1$ .  $\square$

**Theorem 2.33.** Let  $k$  be a natural number. Then there exists a natural number  $n$  (which will be much larger than  $k$ ) such that no natural number less than  $k$  and greater than 1 divides  $n$ .

*Proof.* Let  $n = \prod_{i=2}^{k-1} (i) + 1$ . For any  $a$  such that  $1 < a < k$ , we find  $a | (n-1)$  (as  $a$  is in the product that defines  $n-1$ ). Since  $(n-1, n) = 1$  by 2.32 and  $a > 1$ , we know that  $a$  cannot be a common factor of  $n-1$  and  $n$ . Since  $a | (n-1)$ , we then conclude  $a \nmid n$ . Thus, no number  $a$  between 1 and  $k$  divides  $n$ .  $\square$

**Theorem 2.34.** Let  $k$  be a natural number. Then there exists a prime larger than  $k$ .

*Proof.* Assume there exists a  $k$  such that no prime is larger than  $k$ . By 2.33, there exists an  $n$  such that no number between 1 and  $k+1$  divides  $n$ . Since all primes are in that range, that means no prime number divides  $n$ . This is a contradiction with 2.7, proving our assumption absurd. Thus, no  $k$  exists such that no prime is larger than  $k$ : in other words, for every  $k$  there exists a prime larger than  $k$ .  $\square$

**Theorem 2.35.** There are infinitely many prime numbers.

*Proof.* Assume there are finitely many primes. Then by 2.34 there is a prime larger than the largest prime. Absurd.  $\square$

**Question 2.36.** What were the most clever or most difficult parts in your proof of the Infintude of Primes Theorem?

The most clever thing I did was take Algebra II BC, so that I had already seen this proof. If you would like to know more go back in time and ask 9th grade me, I don't remember this being that difficult but I was more heavily guided then.

**Theorem 2.37.** If  $r_1, r_2, \dots, r_m$  are natural numbers and each one is congruent to 1 modulo 4, then the product  $r_1 r_2 \cdots r_m$  is also congruent to 1 modulo 4.

*Proof.*  $r_1 r_2 \cdots r_m \equiv 1 \cdot 1 \cdots 1 \equiv 1 \pmod{4}$ .  $\square$

**Theorem 2.38.** There are infinitely many prime numbers that are congruent to 3 modulo 4.

*Proof.* Let's say that  $n$  is the biggest prime that is congruent to 3 modulo 4. Let  $m = \prod_{p \in \mathbb{P}}^n p$ .

Notice that  $2 | m$  (as there is a factor of 2 in the product) but  $4 \nmid m$  (since  $2 \nmid (m/2)$ , as  $(m/2)$ 's prime factorization has no remaining 2's). Thus,  $m \equiv 2 \pmod{4}$ .

Let us examine  $m+1$ . We know that  $m+1 \equiv 3 \pmod{4}$ . We also know that, since no prime less than or equal to  $n$  divides  $m+1$  and  $n$  is the biggest prime such that  $n \equiv 3 \pmod{4}$ , no prime that is equivalent to 3 modulo 4 divides  $m+1$ .

Notice that  $m+1$  must have a prime factorization that includes at least 1 prime that is equivalent to 3 modulo 4 (as by 2.37 the product solely of primes that are equivalent to 1 will also be equivalent to 1, which  $m+1$  is not). The prime factors of  $m+1$  cannot be equivalent to 0 or 2 (as there are no primes divisible by 4 and thus none equivalent to 0, and there is only one even prime that is equivalent to 2 we already know  $2 \nmid (m+1)$ ). Thus, there has to be a prime that is equivalent to 3 modulo 4 in the prime factorization.

Since this number cannot be any prime between 0 and  $n$ , we've found a prime greater than  $n$  that is equivalent to 3 modulo 4.

Thus, our assumption that a biggest prime congruent to 3 modulo 4 is false. Thus, since at least one prime congruent to 3 modulo 4 exists (3, for example), there must be infinitely many such primes.  $\square$

**Question 2.39.** *Are there other theorems like the previous one that you can prove?*

There should be, given I caught part of Nir's talk last year, but I have an awful memory.

You can pretty directly use the above technique to show that there are infinitely many primes that *aren't* equivalent to 1 modulo basically-any-number.

You could use this to show there are infinitely many primes congruent to 5 modulo 6, as said primes can't be congruent to 2, 3, 4, or (as goes without saying) 0 and have to be *something* other than 1. Highly composite numbers like 12 are also probably good for this (in this case, we conclude there are infinitely many primes that are either 5, 7, or 11 modulo 12).

**Exercise 2.40.** *Find the current record for the longest arithmetic progression of primes.*

It seems to be 27 primes, discovered in 2019 by Rob Gahan and... PrimeGrid? I assume that's some kind of distributed computing project.

$224584605939537911 + 81292139 \cdot 23\# \cdot n$ , for  $0 \leq n < 27$ .

(For a prime  $p$ , the primorial  $p\#$  is  $2 \cdot 3 \cdot 5 \cdot 7 \cdot 11 \cdot \dots \cdot p$ .)

## Primes of special form

**Exercise 2.41.** *Use polynomial long division to compute  $(x^m - 1) \div (x - 1)$ .*

$$x^{m-1} + x^{m-2} + \dots + x + 1 = \sum_{i=0}^{m-1} x^i$$

**Theorem 2.42.** *If  $n$  is a natural number and  $2^n - 1$  is prime, then  $n$  must be prime.*

*Proof.* Assume  $n = ab$ . To show  $n$  is prime, we will show that  $a$  and  $b$  can only be 1 and  $n$ : to do this, we will show that  $a$  must either be 1 or  $n$ , and then  $b$  must be the opposite choice to satisfy  $n = ab$ .

$2^n - 1 = 2^{ab} - 1 = (2^a)^b - 1 = \frac{(2^a)^b - 1}{2^a - 1} (2^a - 1)$ . By 2.41 (with  $x = 2^a$  and  $m = b$ ) we find this is equal to  $((2^a)^{b-1} + (2^a)^{b-2} + \dots + 1) \cdot (2^a - 1)$ . Since this product of integers is equal to  $2^n - 1$ , which is prime, we conclude that the integers are 1 and  $2^n - 1$ .

This leaves us with two possibilities for what  $2^a - 1$  could be: 1 or  $2^n - 1$ . In the case  $2^a - 1 = 1$ , we find  $2^a = 2 \implies a = 1$ . In the case  $2^a - 1 = 2^n - 1$ , we find  $2^a = 2^n \implies a = n$ . Thus, for any integers  $a$  and  $b$  such that  $n = ab$ , we've found that  $a$  and  $b$  must be 1 and  $n$ : in other words,  $n$  is prime.  $\square$

**Theorem 2.43.** *If  $n$  is a natural number and  $2^n + 1$  is prime, then  $n$  must be a power of 2.*

*Proof.* Notice that  $n$  is a power of 2 if and only if it has no odd divisors other than 1 (if  $n$  isn't a power of 2, its prime factorization contains an odd number or it is 1; if  $n$  is a power of 2, it has no odd divisors other than 1 by 2.12).

Let  $n = ab$ , where  $b$  is an odd number. Such a factorization will always exist because we can always take  $b = 1$  and  $a = n$ .

$2^n + 1 = 2^{ab} + 1 = (2^a)^b + 1 = \frac{(2^a)^b + 1}{2^a + 1} (2^a + 1)$ . By polynomial long division (do it yourself), we find this is equal to  $((2^a)^{b-1} - (2^a)^{b-2} + \dots + 1) \cdot (2^a + 1)$  (the final 1 in the first term is positive because  $b$  is odd, not that it matters). As before, since this product of integers is equal to  $2^n + 1$ , a prime, we conclude the integers are 1 and  $2^n + 1$ .

We know  $2^a + 1 \neq 1$  because that would imply  $2^a = 0$ , which is impossible. Thus, we conclude  $2^a + 1 = 2^n + 1 = 2^{ab} + 1$ , implying  $a = ab \implies b = 1$ . Thus, the only odd number that divides  $n$  is 1. In other words,  $n$  is a power of 2.  $\square$

**Exercise 2.44.** *Find the first few Mersenne primes and Fermat primes.*

Mersenne: 3, 7, 31, 127.

Fermat: 3, 5, 17, 257.

**Exercise 2.45.** *For an A in the class and a Ph.D. in mathematics, prove that there are infinitely many Mersenne primes (or Fermat primes) or prove that there aren't (your choice).*

Our traditional approach of assuming there are finitely many Mersenne primes and then constructing a new one is flawed because there doesn't seem to be a way to create a product of said Mersenne primes that we can then modify to get a new Mersenne prime (or multiple of a new Mersenne prime).

I think what would really help us would be some way to tell if  $2^n - 1$  is prime in terms of  $n$ , so that we could more easily prove the infinitude or finitude of the set of exponents. We know that  $n$  must be prime, but that isn't sufficient (e.g.  $2^{11} - 1 = 2047 = 23 \cdot 89$ ).

## The distribution of primes

**Theorem 2.46.** *There exist arbitrarily long strings of consecutive composite numbers. That is, for any natural number  $n$  there is a string of more than  $n$  consecutive composite numbers.*

*Proof.* For any  $n$ , define  $k$  as follows.

$$k = \prod_{p \in \mathbb{P}}^{n+1} p^{\lceil \log_p(n+1) \rceil}$$

We will show that the string  $k + 2 \dots k + n + 1$  is a string of  $n$  consecutive composite numbers. In other words, for all  $i$  with  $2 \leq i \leq (n + 1)$ , there exists some  $p \neq k + i$  such that  $p | (k + i)$ .

In fact, we will show that such a  $p$  is less than or equal to  $n$  (this obviously implies  $p \neq k + i$  given that  $k + i > n$ ).

Let us examine the prime factorization of  $i$ . Since it is less than or equal to  $n + 1$ , we know that its prime factors are also less than or equal to  $n + 1$ . In fact, for any term  $p_i^{r_i}$  in the prime factorization, we know  $p_i^{r_i} \leq i \leq n + 1 = p_i^{\log_{p_i}(n+1)}$ , implying that  $r_i \leq \log_{p_i}(n + 1) \leq \lceil \log_{p_i}(n + 1) \rceil$ . By 2.12, we then notice that  $i | k$  (as  $k$ 's prime factorization is equal to its definition above). Thus, we can write  $k + i$  as  $i \cdot (\frac{k}{i} + 1)$ , where  $\frac{k}{i} + 1$  is an integer. Thus we conclude  $i | (k + i)$ , and since  $i \neq 1$  as  $2 \leq i$  and  $i \neq k + 1$  because  $k \neq 0$  (something something irrelevant edge case where  $n$  is small) we conclude that  $k + i$  is composite, as it has a factor that is neither 1 nor itself.

Thus, the sequence  $k + 2 \dots k + n + 1$  is a string of  $n$  consecutive composite numbers for any  $n$ .  $\square$

**Question 2.47.** *Are there infinitely many pairs of primes that differ from one another by two?*

My gut says no, for the same reason the result above is intuitive: as you go higher the list of primes gets longer, they seem to “cover more ground” and the proportion of numbers that are composite goes up.

Apparently it's been proven that for some integer  $N$  less than 246 there are infinitely many primes that differ by  $N$ , though, so that intuition goes out the window. Hrm.

The main problem with the product-building we've been doing so far is that if you made some product  $m$  you'd have to show that, for example, both  $m + 1$  AND  $m + 3$  are prime, and the  $m + 3$  case complicates things (obviously  $m$  cannot include 3, for example, but then how do you know  $m + 1$  isn't divisible by 3?). Plus, what would your product even be? I suppose you could show there's a pair of twin primes higher than any  $k$  by forming  $m = \prod_{p \in \mathbb{P}}^k$ , although then you'd have to divide that by 3 as mentioned before and THEN show  $m + 3$  is prime. In fact, I'm not entirely sure you could then show  $m + 1$  is prime, because you have to show it's not divisible by 3 which seems... hard, especially since there are infinitely primes that are either 1 or 2 modulo 3.

**Exercise 2.48.** *Express each of the first 20 even numbers greater than 2 as a sum of two primes.*

$$\begin{aligned} 4 &= 2 + 2, 6 = 3 + 3 \\ 8 &= 5 + 3, 10 = 5 + 5 \\ 12 &= 7 + 5, 14 = 7 + 7 \\ 16 &= 11 + 5, 18 = 11 + 7 \\ 20 &= 13 + 7, 22 = 17 + 5 \\ 24 &= 17 + 7, 26 = 19 + 7 \\ 28 &= 19 + 7, 30 = 17 + 13 \\ 32 &= 19 + 13, 34 = 17 + 17 \\ 36 &= 19 + 17, 38 = 19 + 19 \\ 40 &= 23 + 17, 42 = 23 + 19 \end{aligned}$$

**Exercise 2.49.** *Find the current record for the largest known Mersenne prime.*

$$2^{82589933} - 1$$

### 3 Chapter 3

#### Powers and polynomials modulo $n$

**Exercise 3.1.** Show that 41 divides  $2^{20} - 1$  by following these steps. Explain why each step is true.

1.  $2^5 \equiv -9 \pmod{41}$  because  $41 \mid 41 = 32 - (-9)$
2.  $(2^5)^4 \equiv (-9)^4 \pmod{41}$  because 1.14
3.  $2^{20} \equiv 81^2 \pmod{41}$  because  $(2^5)^4 = 2^{5 \cdot 4} = 2^{20}$  and  $(-9)^4 = ((-9)^2)^2 = 81^2$
4.  $2^{20} - 1 \equiv 0 \pmod{41}$  because  $81 \equiv -1 \pmod{41}$  so  $81^2 \equiv 1 \pmod{41}$  so  $2^{20} \equiv 1 \pmod{41}$

**Question 3.2.** In your head, can you find the natural number  $k$ ,  $0 \leq k \leq 11$ , such that  $k \equiv 37^{453} \pmod{12}$ ?

1

**Question 3.3.** In your head or using paper and pencil, but no calculator, can you find the natural number  $k$ ,  $0 \leq k \leq 6$ , such that  $2^{50} \equiv k \pmod{7}$ ?

4

**Question 3.4.** Using paper and pencil, but no calculator, can you find the natural number  $k$ ,  $0 \leq k \leq 11$ , such that  $39^{453} \equiv k \pmod{12}$ ?

3

**Exercise 3.5.** Show that 39 divides  $17^{48} - 5^{24}$

So open up python and... no? Fine.

Notice (via calculator) that  $17^2 \equiv 16 \pmod{39}$ . Then,  $17^3 \equiv 16 \cdot 17 \equiv -1 \pmod{39}$ . From there we obtain  $17^4 \equiv -17$  and  $17^5 \equiv -16$  before arriving at  $17^6 \equiv 1$ . This cycle then repeats: we notice that 48 is a multiple of 6, so  $17^{48} \equiv 1 \pmod{39}$ .

Similarly,  $5^4 \equiv 1 \pmod{39}$  so we find  $5^{24} \equiv 1$ . Then we know  $17^{48} \equiv 5^{24} \pmod{39}$ , so definitionally  $39 \mid (17^{48} - 5^{24})$ .

**Question 3.6.** Let  $a$ ,  $n$ , and  $r$  be natural numbers. Describe how to find the number  $k$  ( $0 \leq k \leq n-1$ ) such that  $k \equiv a^r \pmod{n}$  subject to the restraint that you never multiply numbers larger than  $n$  and that you only have to do about  $\log_2(r)$  such multiplications.

Get a computer to do it.

Failing that, or if you're the poor soul who has to program the computer, you start off by essentially making a library of powers of  $a$  in their "simplest form" modulo  $n$ . So you start with  $a \equiv x_0 \pmod{n}$  (where in most cases if  $a < n$  we find  $x_0 = a$ , but then you square  $a$  and then pair down the result to something between 0 and  $n$  (probably using the division algorithm) to get  $a^2 \equiv x_1$ , then square that to get  $a^4 \equiv x_2$ ,  $a^8 \equiv x_3$ , etc. etc. until you've build up to  $x_{\lfloor \log_2(r) \rfloor}$ . Then add together the relevant terms from largest to smallest (e.g.  $a^{39} \equiv a^{32} + a^4 + a^2 + a \equiv x_5 + x_2 + x_1 + x_0$ ).

**Theorem 3.14.** Given any integer  $a$  and any natural number  $n$ , there exists a unique integer  $t$  in the set  $\{0, 1, 2, \dots, n-1\}$  such that  $a \equiv t \pmod{n}$ .

*Proof.* By division algorithm, we find  $a = qn + r$  with  $0 \leq r \leq n-1$ . Notice  $qn = a - r$  implies  $n \mid (a - r)$  implies  $a \equiv r \pmod{n}$  with  $0 \leq r \leq n-1$ , so the existence of such a  $t$  is shown.

Say there exist  $t_1, t_2$  in the set  $\{0, \dots, n-1\}$  such that  $a \equiv t_1 \pmod{n}$  and  $a \equiv t_2 \pmod{n}$ . Then  $t_1 \equiv t_2 \pmod{n}$  by 1.11. Then  $n \mid (t_1 - t_2)$ . However, since  $0 \leq t_1, t_2 \leq n-1$ , we find  $-n+1 \leq t_1 - t_2 \leq n-1$ . The only number that  $n$  divides in that range is 0, so we conclude  $t_1 - t_2 = 0$  or  $t_1 = t_2$ , proving that such a  $t$  is unique.  $\square$

**Exercise 3.15.** Find three complete residue systems modulo 4: the canonical complete residue system, one containing negative numbers, and one containing no two consecutive numbers.

CCRS (canonical complete residue system):  $\{0, 1, 2, 3\}$ .

CRSCNN (complete residue system containing negative numbers):  $\{-4, -3, -2, -1\}$ .

CRSCNTCN (complete residue system containing no two consecutive numbers):  $\{0, 5, 2, 7\}$ .

**Theorem 3.16.** *Let  $n$  be natural number. Every complete residue system modulo  $n$  contains  $n$  elements.*

*Proof.* Well we know that the quotient group  $\mathbb{Z}/n\mathbb{Z}$  has... no? Fine.

If a CRS has more than  $n$  elements, by invoking 3.14 repeatedly we find by pigeonhole principle there have to be two elements of the CRS (call them  $a$  and  $b$ ) that are equivalent to the same member of the set  $\{0, \dots, n-1\}$ . By 1.11, we then find  $a \equiv b \pmod{n}$ . Then it's impossible for every integer to be congruent to exactly one member of the set, because we find  $a \equiv a \pmod{n}$  and  $a \equiv b \pmod{n}$ , so our CRS is not a CRS at all. Thus, all CRS's will have  $n$  or fewer elements.

If a CRS has fewer than  $n$  elements, if we invoke 3.14 on all of its elements it won't "fully cover" the set  $\{0, \dots, n-1\}$ . Let  $x$  be the uncovered element. It's impossible for  $x$  to be congruent to any of the elements of the CRS, since by 3.14 all of the elements of the CRS are congruent to *exactly* one element of  $\{0, \dots, n-1\}$  and so they can't be congruent to both the element we "covered" earlier and to  $x$ . Thus, our CRS is not a CRS at all, and we conclude all CRS's will have  $n$  or more elements.

Since the size of any CRS is greater than  $n-1$  and less than  $n+1$ , we conclude that all CRS's are of size  $n$ .  $\square$

**Theorem 3.17.** *Let  $n$  be a natural number. Any set,  $A = \{a_1, a_2, \dots, a_n\}$  of  $n$  integers for which no two are congruent modulo  $n$  is a complete residue set.*

*Proof.* If we invoke 3.14 on all of the members of  $A$  we will get exactly the elements of  $S = \{0, \dots, n-1\}$  (we cannot hit any element twice because then we would have two members of  $A$  that are congruent by 1.11, and we cannot hit any element outside of  $S$  because of 3.14). Then by 3.14 and 1.11, we notice that every integer is congruent to exactly one element in  $S$ , and thus it must be congruent to its corresponding element in  $A$  and only that element of  $A$  (or else it would be congruent to two elements of  $S$ , too).  $\square$

## Linear congruences

**Exercise 3.18.** *Find all solutions in the appropriate canonical complete residue system modulo  $n$  that satisfy the following linear congruences.*

1.  $26x \equiv 14 \pmod{3}$  solution is 1
2.  $2x \equiv 3 \pmod{5}$  solution is 4
3.  $4x \equiv 7 \pmod{8}$  no solution
4.  $24x \equiv 123 \pmod{213}$  Work deferred

**Theorem 3.19.** *Let  $a$ ,  $b$ , and  $n$  be integers with  $n > 0$ . Show that  $ax \equiv b \pmod{n}$  has a solution if and only if there exist integers  $x$  and  $y$  such that  $ax + ny = b$ .*

*Proof.*  $ax \equiv b \pmod{n}$  if and only if there exists some integer (call it  $-y$ ) such that  $n(-y) = ax - b$  (by definition). Rearranging this, we find this statement is equivalent to saying that  $ax + ny = b$ .  $\square$

**Theorem 3.20.** *Let  $a$ ,  $b$ , and  $n$  be integers with  $n > 0$ . The equation  $ax \equiv b \pmod{n}$  has a solution if and only if  $(a, n) | b$ .*

*Proof.* The equation has a solution if and only if there exist integers such that  $ax + ny = b$  (3.19), which occurs if and only if  $(a, n) | b$  (1.48).  $\square$

**Question 3.21.** *What does the preceding theorem tell us about the congruence (4) in Exercise 3.18 above?*

Since  $(24, 213) = 3$  and  $3 | 123$ , it tells us that such a congruence exists.

**Exercise 3.22.** *Use the Euclidean Algorithm to find a member  $x$  of the canonical complete residue system modulo 213 that satisfies  $24x \equiv 123 \pmod{213}$ . Find all members  $x$  of the canonical complete residue system modulo 213 that satisfy  $24x \equiv 123 \pmod{213}$ .*

This problem is equivalent to finding integers  $x, y$  such that  $24x + 213y = 123$ , with the limitation that  $0 \leq x < 213$ .

$213 = 8 \cdot 24 + 21$ , giving  $21 = 213 + (-8) \cdot 24$

$24 = 21 + 3$ , giving  $3 = 24 + (-1) \cdot 21$ .

Combining these two, we get  $3 = 9 \cdot 24 - 213$ .

Then, we multiply both sides by 41 to get  $123 = 369 \cdot 24 - 41 \cdot 213$ .

By 1.53, we've found that the number multiplying 24 in the equation  $24x + 213y = 123$  (and thus every solution to  $24x \equiv 123 \pmod{213}$ ) is of the form  $369 - 71k$  for some integer  $k$ . The possible values this gives us in the range from 0 to 212 are 14, 85, and 156.

**Question 3.23.** Let  $a$ ,  $b$ , and  $n$  be integers with  $n > 0$ . How many solutions are there to the linear congruence  $ax \equiv b \pmod{n}$  in the canonical complete residue system modulo  $n$ ? Can you describe a technique to find them?

I played around with it a bit but just got 3.24 so I'll tex my proof there instead.

**Theorem 3.24.** Let  $a$ ,  $b$ , and  $n$  be integers with  $n > 0$ . Then

1. The congruence  $ax \equiv b \pmod{n}$  is solvable in integers if and only if  $(a, n) | b$ ;
2. If  $x_0$  is a solution to the congruence  $ax \equiv b \pmod{n}$ , then all solutions are given by

$$x_0 + \left( \frac{n}{(a, n)} \cdot m \right) \pmod{n}$$

for  $m = 0, 1, 2, \dots, (a, n) - 1$ ; and

3. If  $ax \equiv b \pmod{n}$  has a solution, then there are exactly  $(a, n)$  solutions in the canonical complete residue system modulo  $n$ .

*Proof.* Notice that, as shown in the proof of 3.19, asking for  $x$ 's in the CCRS mod  $n$  satisfying  $ax \equiv b \pmod{n}$  is equivalent to asking for  $x$ 's such that  $0 \leq x \leq n - 1$  and  $ax + ny = b$  for some integer  $y$ . From here we basically copy-paste all the hard work our previous selves did in chapter 1 (what suckers).

First of all, part 1 here is just 3.20, so that's done.

Second, part 2 is basically just 1.53, since we know all solutions will be of the form  $x_0 + \left( \frac{n}{(a, n)} \cdot m \right)$  for some  $m$  in the integers. That all solutions are covered by  $m = 0, \dots, (a, n) - 1$  is proven by part 3 (which we haven't shown yet, but we will, and we won't use this fact to prove part 3 so don't worry about circularity): if there have to be  $(a, n)$  values, they must be covered by the first  $(a, n)$  possibilities of  $m$  because if they weren't that would imply that two different values had to lead to the "same" product modulo  $n$  to only use  $(a, n) - 1$  solutions with  $(a, n)$  values, and that would cause the future products to keep going around in a cycle. For example, if  $m = 1$  and  $m = 4$  lead to the same solution, then so would  $m = 2$  and  $m = 5$ , and so would  $m = 3$  and  $m = 6$ , etc., and there would be no  $(a, n)$ -th solution.

Finally, part 3 comes from the fact that there are  $n$  possibilities for  $x$ , and we get all the possibilities by "moving" in increments of  $n/(a, n)$ . In this way, we can basically imagine that each possibility of  $x$  is "occupying"  $n/(a, n)$  possible numbers. To get the total number of real possibilities, then, we take  $n$  and divide by  $n/(a, n)$  to get  $(a, n)$ , the number of real values of  $x$  needed to "cover" every possibility between 0 and  $n - 1$ . Does that make sense? I hope so.  $\square$

## Systems of linear congruences: the Chinese Remainder Theorem

**Exercise 3.25.** A band of 17 pirates stole a sack of gold coins. When they tried to divide the fortune into equal portions, 3 coins remained. In the ensuing brawl over who should get the extra coins, one pirate was killed. The coins were redistributed, but this time an equal division left 10 coins. Again they fought about who should get the remaining coins and another pirate was killed. Now, fortunately, the coins could be divided evenly among the surviving 15 pirates. What was the fewest number of coins that could have been in the sack?

This would never happen. In all likelihood, the coins would simply be put in the ship's treasury to pay for injured pirates' medical expenses and/or send money to family of pirates killed in battle.

The number of coins must be a multiple of 15. Call it  $15k$ .

Then, we know  $15 \equiv 10 \pmod{16}$ . From this, since  $15 \equiv -1$  and  $10 \equiv -6$ , we find  $(-1)k \equiv -6$ . Multiplying both sides by  $-1$ , we get  $k \equiv 6 \pmod{16}$ .

Similarly,  $15k \equiv 3 \pmod{17}$ , so  $(-2)k \equiv -14$ . Multiplying both sides by 8, we get  $k \equiv -112 \equiv 7 \pmod{17}$ .

Since  $k \equiv 6 \pmod{16}$ , we know  $k$  is of the form  $16x + 6$ . Since  $k \equiv 7 \pmod{17}$ , we conclude  $16x \equiv 7 \pmod{17}$ , implying  $16x \equiv 1$ . Then, since  $16 \equiv -1 \pmod{17}$ , we conclude  $-1x \equiv 1 \pmod{17}$ , or  $x \equiv -1 \equiv 16 \pmod{17}$ .

Since we're trying to minimize  $15k$ , we're trying to minimize  $k$ . Similarly, that means we're trying to minimize  $16x + 6$ , so we can obtain our answer by minimizing  $x$ . The smallest positive integer (since there are more than 0 coins) that is equivalent to 16 modulo 17 is 16, so plugging that in we obtain  $k = 16 \cdot 16 + 6 = 262$  and then  $15k = 15 \cdot 262 = 3930$ .

**Exercise 3.26.** When eggs in a basket are removed two, three, four, five, or six at a time, there remain, respectively, one, two, three, four, or five eggs. When they are taken out seven at a time, none are left over. Find the smallest number of eggs that could have been contained in the basket.

Notice that if we added one more egg, the number of eggs would be divisible by two, three, four, five, and six. Thus, its prime factorization would have to include  $2^2 3^1 5^1$ . In other words, it would have to be multiple of 60. Thus, the number of eggs has to be one less than a multiple of 60. Call it  $60x - 1$ .

We know  $7 | (60x - 1)$ . Thus,  $60x \equiv 1 \pmod{7}$ . Noticing  $60 \equiv 4 \pmod{7}$ , we conclude  $4x \equiv 1 \pmod{7}$ . Multiplying both sides by 2 we obtain  $x \equiv 2 \pmod{7}$ . To minimize  $60x - 1$ , we minimize  $x$ : in this case, the smallest possible value is  $x = 2$ . Plugging that in, we get  $60 \cdot 2 - 1 = 119$ .

**Theorem 3.27.** Let  $a, b, m$ , and  $n$  be integers with  $m > 0$  and  $n > 0$ . Then the system

$$\begin{aligned} x &\equiv a \pmod{n} \\ x &\equiv b \pmod{m} \end{aligned}$$

has a solution if and only if  $(n, m) | a - b$ .

*Proof.* Every step in this proof will be bidirectional.

$x \equiv a \pmod{n}$  and  $x \equiv b \pmod{m}$  can be rewritten as  $ny = x - a$  and  $mz = x - b$  for some integers  $y$  and  $z$ . This implies  $mz = ny + a - b$ , rewritten as  $n(-y) + mz = a - b$  for some integers  $y$  and  $z$ . By 1.48, said integers  $y$  and  $z$  exist if and only if  $(n, m) | a - b$ .  $\square$

**Theorem 3.28.** Let  $a, b, m$ , and  $n$  be integers with  $m, n > 0$ , and  $(m, n) = 1$ . Then the system

$$\begin{aligned} x &\equiv a \pmod{n} \\ x &\equiv b \pmod{m} \end{aligned}$$

has a unique solution modulo  $mn$ .

*Proof.* We will conjure two solutions to this system,  $x_1$  and  $x_2$ , and show they are congruent modulo  $nm$ .

Notice  $x_1 \equiv a \pmod{n}$  implies  $ny_1 = x_1 - a$  for some integer  $y_1$ . Similarly, we find  $mz_1 = x_1 - b$ ,  $ny_2 = x_2 - a$ , and  $mz_2 = x_2 - b$ .

Take  $ny_1 = x_1 - a$  and subtract  $ny_2 = x_2 - a$  to obtain  $ny_1 - ny_2 = x_1 - a - (x_2 - a)$ . With some rearrangement, we find  $n(y_1 - y_2) = x_1 - x_2$ , so we conclude  $n | (x_1 - x_2)$ .

Similarly, taking  $mz_1 = x_1 - b$  and subtracting  $mz_2 = x_2 - b$  gives us  $m(z_1 - z_2) = x_1 - x_2$ , implying  $m | (x_1 - x_2)$ .

By 1.42, since  $(n, m) = 1$ , we conclude  $nm | (x_1 - x_2)$ . By definition, this means  $x_1 \equiv x_2 \pmod{nm}$ , and we're done.  $\square$

**Theorem 3.29.** Suppose  $n_1, n_2, \dots, n_L$  are positive integers that are pairwise relatively prime, that is,  $(n_i, n_j) = 1$  for  $i \neq j$ ,  $1 \leq i, j \leq L$ . Then the system of  $L$  congruences

$$\begin{aligned} x &\equiv a_1 \pmod{n_1} \\ x &\equiv a_2 \pmod{n_2} \\ &\vdots \\ x &\equiv a_L \pmod{n_L} \end{aligned}$$

has a unique solution modulo the product  $n_1 n_2 n_3 \cdots n_L$ .

*Proof.* The proof is by induction. The base case is  $L = 2$ , which is 3.28.

Our induction hypothesis is that for all natural numbers  $b < L$ , it is the case that yadda yadda yadda I'm not writing all that out again. We will then show that for a system of  $L$  simultaneous equations, the theorem holds.

Take the first  $L - 1$  equations from our system. We have a grouping that looks like

$$\begin{aligned} x &\equiv a_1 \pmod{n_1} \\ &\vdots \\ x &\equiv a_{L-1} \pmod{n_{L-1}} \end{aligned}$$

which, by our induction hypothesis, has a unique solution modulo  $N = n_1 n_2 \cdots n_{L-1}$ . Call this solution  $x_0$ . Now we examine the system

$$\begin{aligned}x &\equiv x_0 \pmod{N} \\x &\equiv a_L \pmod{L}\end{aligned}$$

which, by our base case, has a unique solution modulo  $NL = n_1 \cdots n_L$ . Since the first equation is equivalent to the first  $L-1$  equations in our original system, we notice that the solutions to this system are exactly the solutions to our original system. Thus, since this system has a unique solution modulo  $n_1 \cdots n_L$ , so does our original system.  $\square$

## 4 Chapter 4

### Orders of an integer modulo $n$

**Exercise 4.1.** For  $i = 0, 1, 2, 3, 4, 5$  and  $6$ , find the number in the CCRS to which  $2^i$  is congruent modulo  $7$ .

1, 2, 4, 1, 2, 4, 1.

**Theorem 4.2.** Let  $a$  and  $n$  be natural numbers with  $(a, n) = 1$ . Then  $(a^j, n) = 1$  for any natural number  $j$ .

*Proof.* I could've sworn we've done this already. In any case, the proof is by induction, with the base case being  $j = 1$  given to us immediately. The hypothesis is  $(a^{j-1}, n) = 1$ , and this in conjunction with the fact that  $(a, n) = 1$  and 2.29 is enough to show  $(a^j, n) = 1$ .  $\square$

**Theorem 4.3.** Let  $a$ ,  $b$ , and  $n$  be integers with  $n > 0$  and  $(a, n) = 1$ . If  $a \equiv b \pmod{n}$ , then  $(b, n) = 1$ .

*Proof.* Since  $a \equiv b \pmod{n}$ , we know  $n|(b - a)$ . Since  $(b, n)|n$ , we conclude  $(b, n)|(b - a)$ . This implies  $(b, n)|(a - b)$ , and since  $(b, n)|b$  we conclude  $(b, n)|a$ . Then we know  $(b, n)$  is a common factor of  $a$  and  $n$ , and so we conclude  $(b, n) \leq 1$ . Thus,  $(b, n) = 1$ .  $\square$

**Theorem 4.4.** Let  $a$  and  $n$  be natural numbers. Then there exist natural numbers  $i$  and  $j$ , with  $i \neq j$ , such that  $a^i \equiv a^j \pmod{n}$ .

*Proof.* Consider the series  $a^1, a^2, a^3, \dots$ . When we take this series and reduce each term to its corresponding member in the CCRS, there are only finitely many values each term can take, but infinitely many terms. Thus, by pigeonhole, two terms must take the same value, and thus two terms must be congruent modulo  $n$ .  $\square$

**Theorem 4.5.** Let  $a$ ,  $b$ ,  $c$ , and  $n$  be integers with  $n > 0$ . If  $ac \equiv bc \pmod{n}$  and  $(c, n) = 1$ , then  $a \equiv b \pmod{n}$ .

*Proof.*  $ac \equiv bc \pmod{n}$  implies  $n|(bc - ac)$ , implying  $n|(c \cdot (b - a))$ . Since  $(c, n) = 1$ , by 1.41 we conclude  $n|(b - a)$ , implying  $a \equiv b \pmod{n}$ .  $\square$

**Theorem 4.6.** Let  $a$  and  $n$  be natural numbers with  $(a, n) = 1$ . Then there exists a natural number  $k$  such that  $a^k \equiv 1 \pmod{n}$ .

*Proof.* By 4.4, we know there exist distinct natural numbers  $i$  and  $j$  such that  $a^i \equiv a^j \pmod{n}$ . Assume WLOG  $j > i$ . By definition, this implies  $n|(a^j - a^i)$ , implying  $n|(a^i \cdot (a^{j-i} - 1))$ .

Since  $(a, n) = 1$ , we invoke 4.2 and find  $(a^i, n) = 1$ . Then, we combine that with  $n|(a^i \cdot (a^{j-i} - 1))$  and invoke 1.41 to conclude  $n|(a^{j-i} - 1)$ , which definitionally implies  $a^{j-i} \equiv 1 \pmod{n}$  for some natural number  $j - i$ .  $\square$

### Fermat's Little Theorem

**Question 4.7.** Choose some relatively prime natural numbers  $a$  and  $n$  and compute the order of  $a$  modulo  $n$ . Frame a conjecture concerning how large the order of  $a$  modulo  $n$  can be, depending on  $n$ .

We covered this in math seminar right? Am I going crazy? Maybe AMR? I'm unsure.

We know  $\text{ord}_n(a)$  divides the number of units of  $n$ , where the units of  $n$  are the numbers in the CCRS that have a multiplicative inverse modulo  $n$ .

**Theorem 4.8.** Let  $a$  and  $n$  be natural numbers with  $(a, n) = 1$  and let  $k = \text{ord}_n(a)$ . Then the numbers  $a^1, a^2, \dots, a^k$  are pairwise incongruent modulo  $n$ .

*Proof.* Say there exist  $1 \leq i, j \leq k$  such that  $a^i \equiv a^j \pmod{n}$ . WLOG, assume  $j > i$ . Then, notice that  $n|(a^j - a^i)$  implies  $n|(a^i \cdot (a^{j-i} - 1))$ , which since  $(n, a^i) = 1$  (4.2) implies  $n|(a^{j-i} - 1)$ , implying  $a^{j-i} \equiv 1 \pmod{n}$  for some  $j - i < k$ .

This is a contradiction, since  $k$  is the *smallest* integer such that  $a^k \equiv 1$ . Thus, our assumption that such  $i$  and  $j$  exist is flawed, and the numbers  $a^1, a^2, \dots, a^k$  are pairwise incongruent.  $\square$

**Theorem 4.9.** Let  $a$  and  $n$  be natural numbers with  $(a, n) = 1$  and let  $k = \text{ord}_n(a)$ . For any natural number  $m$ ,  $a^m$  is congruent modulo  $n$  to one of the numbers  $a^1, a^2, \dots, a^k$ .

*Proof.* By division algorithm,  $m = kq + r$  for some integers  $q, r$  with  $r < k$ . Then, we find  $a^m \equiv a^{kq+r} \equiv a^{kq} \cdot a^r \equiv (a^k)^q \cdot a^r \equiv 1^q \cdot a^r \equiv a^r \pmod{n}$  for some  $0 \leq r \leq k - 1$ . Our one edge case is  $a^m \equiv a^0 \equiv 1$ , but we can clearly see this implies  $a^m \equiv a^k$ , and we're done.  $\square$

**Theorem 4.10.** Let  $a$  and  $n$  be natural numbers with  $(a, n) = 1$ , let  $k = \text{ord}_n(a)$ , and let  $m$  be a natural number. Then  $a^m \equiv 1 \pmod{n}$  if and only if  $k|m$ .

*Proof.* Seeing that  $k|m$  implies  $a^m \equiv 1 \pmod{n}$  is easy:  $a^m \equiv a^{kx} \equiv (a^k)^x \equiv 1^x \equiv 1 \pmod{n}$ , for some integer  $x$ .

To show  $a^m \equiv 1 \pmod{n}$  implies  $k|m$ , we invoke the division algorithm and find  $q, r$  such that  $m = kq + r$  for some  $0 \leq r < k$ . Notice  $1 \equiv a^m \equiv a^{kq+r} \equiv a^{kq} \cdot a^r \equiv (a^k)^q \cdot a^r \equiv 1^q \cdot a^r \equiv a^r \pmod{n}$ . Since  $a^r \equiv 1 \pmod{n}$ , we conclude  $r$  isn't between 1 and  $k-1$  inclusive, as then  $k$  wouldn't be the *smallest* number such that  $a^k \equiv 1 \pmod{n}$ . Thus, since  $0 \leq r < k$ , the only remaining possibility is that  $r = 0$ . Thus,  $m = kq + r$  becomes  $m = kq + 0 = kq$ , implying  $k|m$ .  $\square$

**Theorem 4.11.** Let  $a$  and  $n$  be natural numbers with  $(a, n) = 1$ . Then  $\text{ord}_n(a) < n$  (unless  $n = 1$ ).

*Proof.* Suppose  $\text{ord}_n(a) \geq n$ . Then, by 4.8, we know  $a^1, a^2, \dots, a^n$  are pairwise incongruent modulo  $n$ . This implies that each of these numbers reduces to a different number in the CCRS modulo  $n$  (if two numbers reduced to the same thing, they'd be congruent). Thus, since the CCRS has  $n$  elements like the sequence, every member of the CCRS must be "hit" by the powers of  $a$ . This implies there exists an  $i$  such that  $a^i \equiv 0 \pmod{n}$ , or in other words  $n|a^i$ . Since  $(a, n) = 1$ , by 4.2 we know  $(a^i, n) = 1$ . Since  $n$  is a common factor of  $n$  and  $a^i$ , we conclude  $n = 1$ . This is the one exception to the theorem: in any other case, we now know  $\text{ord}_n(a) < n$ .  $\square$

**Exercise 4.12.** Compute  $a^{p-1} \pmod{p}$  for various numbers  $a$  and primes  $p$ , and make a conjecture.

$$a = 4, p = 5, 4^{5-1} \equiv 1 \pmod{5}.$$

$$a = 3, p = 5, 3^{5-1} \equiv 1 \pmod{5}.$$

$$a = 4, p = 7, 4^{7-1} \equiv 1 \pmod{7}.$$

$$a = 3, p = 7, 3^{7-1} \equiv 1 \pmod{7}.$$

$$\text{It seems like } a^{p-1} \equiv 1 \pmod{p}.$$

**Theorem 4.13.** Let  $p$  be a prime and let  $a$  be an integer not divisible by  $p$ ; that is,  $(a, p) = 1$ . Then  $A = \{a, 2a, 3a, \dots, pa\}$  is a complete residue system modulo  $p$ .

*Proof.* By 3.17, we only have to show that no two members of  $A$  are congruent modulo  $p$ . To do this, take any two members  $ia$  and  $ja$ , and assume WLOG that  $j > i$ . Since  $0 < j - i < p$ , we know  $p \nmid (j - i)$ , and we also know  $p \nmid a$ . Thus, by 2.27, we know  $p \nmid (j - i)a$ , or in other words  $p \nmid (aj - ai)$ . By definition, this implies  $aj \not\equiv ai \pmod{p}$ , so the members of  $A$  are pairwise incongruent and this (along with the fact that  $A$  has  $p$  elements) implies  $A$  is a complete residue system.  $\square$

**Theorem 4.14.** Let  $p$  be a prime and let  $a$  be an integer not divisible by  $p$ . Then

$$a \cdot 2a \cdot 3a \cdots (p-1)a \equiv 1 \cdot 2 \cdot 3 \cdots (p-1) \pmod{p}$$

*Proof.* By 4.13, we know the set  $\{a, 2a, \dots, pa\}$  is a CRS. Because of this, when we take the members of this set and "reduce" them to their CCRS members, we should exactly cover the CCRS. Now we kick out  $pa$ , since we know  $pa \equiv 0 \pmod{p}$  (since  $p|pa$ ). Goodbye,  $pa$ . What we're left with is a set that has one term equivalent to 1 modulo  $p$ , one term equivalent to 2 modulo  $p$ , etc., all the way up to a term equivalent to  $p-1$  modulo  $p$ .

Now, we take the product  $a \cdots (p-1)a$  and replace each term with its corresponding member of the CCRS. This won't change what it's congruent to mod  $p$ , since we're replacing things that are equivalent mod  $p$ . What we'll be left with, then, is  $1 \cdot 2 \cdots p-1$ , albeit probably not in that order.  $\square$

**Theorem 4.15.** If  $p$  is a prime and  $a$  is an integer relatively prime to  $p$ , then  $a^{p-1} \equiv 1 \pmod{p}$ .

*Proof.* By 4.14, we know  $a \cdot 2a \cdots (p-1)a \equiv 1 \cdot 2 \cdots (p-1) \pmod{p}$ . With some simple rearrangement, we see  $a^{p-1} \cdot (1 \cdots (p-1)) \equiv 1 \cdot (1 \cdots (p-1))$ . Notice, then, that by 2.12 and the fact that  $p$  is prime we know that  $1 \cdots (p-1)$  is relatively prime to  $p$ . By 4.5, we conclude  $a^{p-1} \equiv 1 \pmod{p}$ .  $\square$

**Theorem 4.16.** If  $p$  is a prime and  $a$  is any integer, then  $a^p \equiv a \pmod{p}$ .

*Proof.* See 4.17 and 4.15.  $\square$

**Theorem 4.17.** *The two versions of Fermat's Little Theorem above are equivalent.*

*Proof.* Showing 4.16 implies 4.15 is as simple as realizing  $a^p \equiv a \pmod{p}$  implies  $a \cdot a^{p-1} \equiv a \cdot 1 \pmod{p}$  and invoking 4.5.

Showing 4.15 implies 4.16 is as simple as multiply both sides of  $a^{p-1} \equiv 1 \pmod{p}$  by  $a \dots$  for  $a$  relatively prime to  $p$ . If  $a$  is not relatively prime to  $p$ , that implies  $p|a$ , so  $a^p \equiv 0 \equiv a \pmod{p}$ , an easy edge case.  $\square$

**Theorem 4.18.** *Let  $p$  be a prime and  $a$  be an integer. If  $(a, p) = 1$ , then  $\text{ord}_p(a)$  divides  $p-1$ , that is,  $\text{ord}_p(a) | p-1$ .*

*Proof.* Since  $a^{p-1} \equiv 1 \pmod{p}$  by 4.15, we cite 4.10 and are done.  $\square$

**Exercise 4.19.** *Compute each of the following without the aid of a calculator or computer.*

1.  $512^{372} \equiv (512^{12})^{31} \equiv 1^{31} \equiv 1 \pmod{13}$ .
2.  $3444^{3233} \equiv (10^{16})^{202} \cdot 10^1 \equiv 1^{202} \cdot 10 \equiv 10 \pmod{17}$ .
3.  $123^{456} \equiv (8^{22})^{20} \cdot 8^{16} \equiv 1^{20} \cdot 18^8 \equiv 2^4 \equiv 4^2 \equiv 8 \pmod{23}$ .

**Exercise 4.20.** *Find the remainder upon division of  $314^{159}$  by 31*

$$314^{159} \equiv (4^{30})^5 \cdot 4^9 \equiv 1^5 \cdot 4^9 \equiv 4 \cdot 16^4 \equiv 4 \cdot 8^2 \equiv 4 \cdot 2 \equiv 8 \pmod{31}$$

**Theorem 4.21.** *Let  $n$  and  $m$  be natural numbers that are relatively prime, and let  $a$  be an integer. If  $x \equiv a \pmod{n}$  and  $x \equiv a \pmod{m}$ , then  $x \equiv a \pmod{nm}$*

*Proof.*  $x \equiv a \pmod{n}$  means  $n|(x-a)$ .  $x \equiv a \pmod{m}$  means  $m|(x-a)$ . Since  $(n, m) = 1$ , we cite 2.25 to get  $nm|(x-a)$ , which means  $x \equiv a \pmod{nm}$ .  $\square$

**Exercise 4.22.** *Find the remainder when  $4^{72}$  is divided by 91 ( $= 7 \cdot 13$ ).*

$$\begin{aligned} 4^{72} &\equiv 2^{36} \equiv 4^{18} \equiv 2^9 \equiv 2 \cdot 4^4 \equiv 2 \cdot 2^2 \equiv 1 \pmod{7}. \\ 4^{72} &\equiv 3^{36} \equiv 9^{18} \equiv 3^9 \equiv 3 \cdot 9^4 \equiv 3 \cdot 3^2 \equiv 1 \pmod{13}. \end{aligned}$$

By 4.21,  $4^{72} \equiv 1 \pmod{91}$ .

**Exercise 4.23.** *Find the natural number  $k < 117$  such that  $2^{117} \equiv k \pmod{117}$ .*

$$2^{117} \equiv 2 \cdot 4^{49} \equiv 2 \cdot 4 \cdot 16^{24} \equiv 8 \cdot 22^{12} \equiv 8 \cdot 16^6 \equiv 8 \cdot 22^3 \equiv 8 \cdot 22 \cdot 16 \equiv 59 \cdot 16 \equiv 8 \pmod{117}$$

## An alternative route to Fermat's Little Theorem

**Theorem 4.24.** *Let  $a$  and  $b$  be numbers and let  $n$  be a natural number. Then*

$$(a+b)^n = \sum_{i=0}^n \binom{n}{i} a^{n-i} b^i$$

*Proof.* The proof is by induction.

Our base case is  $n = 1$ . Notice  $(a+b)^1 = a^1 + b^1$ . Yep. Neat.

Our induction hypothesis is that the formula holds for  $n-1$ . Our inductive step will show it for  $n$ .

Since  $(a+b)^n = (a+b) \cdot (a+b)^{n-1}$ , we cite our induction hypothesis to get  $(a+b) \cdot \sum_{i=0}^{n-1} \binom{n-1}{i} a^{n-1-i} b^i$ .

Distributing over the  $a+b$  term and then distributing over the sigma, we get  $\sum_{i=0}^{n-1} \binom{n-1}{i} a^{n-i} b^i + \sum_{i=0}^{n-1} \binom{n-1}{i} a^{n-1-i} b^{i+1}$ .

Let's shift the index on that second term. Also, we'll use the fact  $\binom{n-1}{0} = 1$  and  $\binom{n-1}{n-1} = 1$  to pull out a couple of edge terms:  $i = 0$  for the first sum, and  $i = n$  for the second. We get  $a^n + \sum_{i=1}^{n-1} \binom{n-1}{i} a^{n-i} b^i + \sum_{i=1}^{n-1} \binom{n-1}{i-1} a^{n-i} b^i + b^n$ .

Now that the indices add up, we combine them into one giant sum. Now we have  $a^n + \sum_{i=1}^{n-1} (\binom{n-1}{i} + \binom{n-1}{i-1}) a^{n-i} b^i + b^n$ .

Using combinatorics knowledge, plus the fact that  $\binom{n}{0} a^{n-0} b^0 = a^n$  and  $\binom{n}{n} a^{n-n} b^n = b^n$ , we combine those binomials and extend the range of the index to get our final result:  $\sum_{i=0}^n \binom{n}{i} a^{n-i} b^i$ .  $\square$

**Theorem 4.25.** *If  $p$  is prime and  $i$  is a natural number less than  $p$ , then  $p$  divides  $\binom{p}{i}$ .*

*Proof.* Binomial are integers, and  $\binom{p}{i} = \frac{p!}{(p-i)!i!}$ . This means  $(p-i)!i! | p!$ . Thus,  $(p-i)!i! | (p \cdot (p-1)!)$ . By 2.12, since  $(p-i)!i!$  has no  $p$ 's in its prime factorization, we know  $(p, (p-i)!i!) = 1$ . Thus, by 1.41, we conclude  $(p-i)!i! | (p-1)!$ .

This means that  $\frac{(p-1)!}{(p-i)!i!}$  is an integer. Since  $p \cdot \frac{(p-1)!}{(p-i)!i!} = \binom{p}{i}$  by the formula above, we've found that  $p$  times some integer is equal to  $\binom{p}{i}$ ; in other words,  $p | \binom{p}{i}$ .  $\square$

**Theorem 4.26.** *If  $p$  is a prime and  $a$  is an integer, then  $a^p \equiv a \pmod{p}$ .*

*Proof.* We do this by induction on  $a$ . Our base case is that  $0^p \equiv 0 \pmod{p}$ . Easy.

Our induction hypothesis is that  $a^p \equiv a \pmod{p}$ , and for our inductive step we want to show  $(a+1)^p \equiv a+1 \pmod{p}$ .

Notice by 4.24 that  $(a+1)^p = \sum_{i=0}^p \binom{p}{i} a^{p-i}$ . Let's see what we can simplify this down to modulo  $p$ .

For each of the terms with  $0 < i < p$ , we know by 4.25 that  $\binom{p}{i} \equiv 0 \pmod{p}$ , so the whole term is congruent to 0. Thus, we can ignore each of these terms, as we're basically just adding a bunch of 0's. With this we simplify down to just  $i = 0$  and  $i = p$ , giving us  $a^p + 1$  (since  $\binom{p}{0} = \binom{p}{p} = 1$ ).

By our inductive hypothesis,  $a^p \equiv a \pmod{p}$ , so we conclude  $(a+1)^p \equiv a^p + 1 \equiv a + 1 \pmod{p}$ , completing our inductive step and the proof.  $\square$

## Euler's Theorem and Wilson's Theorem

**Question 4.27.** *The numbers 1, 5, 7, and 11 are all natural numbers that are relatively prime to 12, so  $\phi(12) = 4$ .*

What is  $\phi(7)$ ? 6.

What is  $\phi(15)$ ? 8.

What is  $\phi(21)$ ? 12.

What is  $\phi(35)$ ? 24.

**Theorem 4.28.** *Let  $a$ ,  $b$ , and  $n$  be integers such that  $(a, n) = 1$  and  $(b, n) = 1$ . Then  $(ab, n) = 1$ .*

*Proof.* Isn't this done with 2.12? Gross, don't make me type out all those subscripts again.  $\square$

**Theorem 4.29.** *Let  $a$ ,  $b$ , and  $n$  be integers with  $n > 0$ . If  $a \equiv b \pmod{n}$  and  $(a, n) = 1$ , then  $(b, n) = 1$ .*

*Proof.*  $(b, n) | n$  and also since  $n | (a - b)$  we conclude  $(b, n) | (a - b)$ . Since  $(b, n) | b$ , we know  $(b, n) | ((a - b) + b)$ , or in other words  $(b, n) | a$ .

Then, since  $(b, n) | n$  and  $(b, n) | a$ , its maximum value is 1. Thus,  $(b, n) = 1$ .  $\square$

**Theorem 4.30.** *Let  $a$ ,  $b$ ,  $c$ , and  $n$  be integers with  $n > 0$ . If  $ab \equiv ac \pmod{n}$  and  $(a, n) = 1$ , then  $b \equiv c \pmod{n}$ .*

*Proof.* Since  $ab \equiv ac \pmod{n}$  we know  $n | (ab - ac)$ , so  $n | a(b - c)$ . If  $(a, n) = 1$ , we know by 1.41 that  $n | (b - c)$ , i.e.  $b \equiv c \pmod{n}$ .  $\square$

**Theorem 4.31.** *Let  $n$  be a natural number and let  $x_1, x_2, \dots, x_{\phi(n)}$  be the distinct natural numbers less than or equal to  $n$  that are relatively prime to  $n$ . Let  $a$  be a non-zero integer relatively prime to  $n$  and let  $i$  and  $j$  be different natural numbers less than or equal to  $\phi(n)$ . Then  $ax_i \not\equiv ax_j \pmod{n}$ .*

*Proof.* Assume WLOG  $x_i > x_j$ .

Since  $0 < x_i - x_j < n$ , we know  $n \nmid (x_i - x_j)$ . Since  $(a, n) = 1$ , we then know  $n \nmid a(x_i - x_j)$ , i.e.  $n \nmid (ax_i - ax_j)$ , i.e.  $ax_i \not\equiv ax_j \pmod{n}$ .  $\square$

**Theorem 4.32.** *If  $a$  and  $n$  are integers with  $n > 0$  and  $(a, n) = 1$ , then*

$$a^{\phi(n)} \equiv 1 \pmod{n}.$$

*Proof.* Let  $\Phi = \{x_1, x_2, \dots, x_{\phi(n)}\}$  be the distinct natural numbers  $\leq n$  that are relatively prime to  $n$ .

To complete this proof, we will first show  $ax_1 \cdots ax_{\phi(n)} \equiv x_1 \cdots x_{\phi(n)} \pmod{n}$ . To see this, take each term of the product on the left side and reduce it to its equivalent term in the CCRS modulo  $n$ . Each of these reduced terms will be distinct (4.31). Since  $(a, n) = 1$ , 2.29 tells us that each term  $ax_i$  is relatively prime to  $n$ . Each term's reduction must then also be relatively prime to  $n$ . To see this, say  $ax_i \equiv \alpha \pmod{n}$ . Then  $n | (ax_i - \alpha)$ , so  $(n, \alpha) | (ax_i - \alpha)$ . Since  $(n, \alpha) | \alpha$ , we conclude  $(n, \alpha) | ax_i$ . This, combined with  $(n, \alpha) | n$ , lets us conclude  $(n, \alpha)$  is a common factor of  $n$  and  $ax_i$ , and thus must be 1.

Thus, when we reduce each of the terms of the product on the left side of our equivalence, we obtain  $\phi(n)$  distinct terms that are all relatively prime to  $n$ . Since there are exactly  $\phi(n)$  possible terms of the CCRS that are relatively prime to  $n$ , this means each possible term must be "covered." In other words, in the product from  $ax_1$  to  $ax_{\phi(n)}$  we have one of each possible term, and by replacing each term on the left with its representation in the CCRS (which we can do when talking about modular congruence) we obtain  $\prod_{i=1}^{\phi(n)} ax_i \equiv \prod_{i=1}^{\phi(n)} x_i \pmod{n}$ .

Taking all of the  $a$ 's out of the left side nets us  $a^{\phi(n)} \cdot (x_1 \cdots x_{\phi(n)}) \equiv 1 \cdot (x_1 \cdots x_{\phi(n)})$ . Since  $x_1 \cdots x_{\phi(n)}$  is a product of numbers relatively prime to  $n$ , we conclude by 2.29 that the product is relatively prime to  $n$ , and thus by 4.5 that  $a^{\phi(n)} \equiv 1 \pmod{n}$ .  $\square$

**Theorem 4.33.** *If  $p$  is a prime and  $a$  is an integer relatively prime to  $p$ , then  $a^{p-1} \equiv 1 \pmod{p}$ .*

*Proof.*  $\phi(p) = p - 1$  since there are  $p - 1$  natural numbers less than  $p$ , and  $p$  is relatively prime to all of them because  $p$  is prime (and obviously doesn't divide any numbers smaller than itself). Then we simply invoke 4.32.  $\square$

**Exercise 4.34.** *Compute each of the following without the aid of a calculator or computer.*

$$12^{49} \equiv 12 \cdot 9^{24} \equiv 12 \cdot 6^{12} \equiv 12 \cdot 6^6 \equiv 12 \cdot 6 \equiv 12 \pmod{15}.$$

$$139^{112} \equiv (4^{18})^4 \cdot 4^4 \equiv 16^2 \equiv 13 \pmod{27}$$

**Exercise 4.35.** *Find the last digit in the base 10 representation of the integer  $13^{474}$*

Make it stop.

$$13^{474} \equiv 3^{474} \equiv (3^4)^{118} \cdot 3^2 \equiv 9 \pmod{10}.$$

**Theorem 4.36.** *Let  $p$  be a prime and let  $a$  be an integer such that  $1 \leq a < p$ . Then there exists a unique natural number  $b$  less than  $p$  such that  $ab \equiv 1 \pmod{p}$ .*

*Proof.* Let  $S = \{1a, 2a, \dots, pa\}$ . By 4.13, this is a CRS. Thus, *exactly* one element must be congruent to 1 modulo  $p$ : call this element  $ba$ .

$$b \neq p \text{ because } pa \equiv 0 \pmod{p}, \text{ and } 0 \not\equiv 1 \pmod{p}.$$

And we're done.  $\square$

**Exercise 4.37.** *Let  $p$  be a prime. Show that the natural numbers 1 and  $p - 1$  are their own inverse modulo  $p$ .*

$$1 \cdot 1 = 1 \equiv 1 \pmod{p}. \text{ Easy.}$$

$$(p - 1) \cdot (p - 1) = p^2 - 2p + 1 \equiv 1 \pmod{p} \text{ (since } (p^2 - 2p + 1) - 1 = p^2 - 2p \text{ and } p|(p^2 - 2p)).$$

**Theorem 4.38.** *Let  $p$  be a prime and let  $a$  and  $b$  be integers such that  $1 < a, b < p - 1$  and  $ab \equiv 1 \pmod{p}$ . Then  $a \neq b$ .*

*Proof.* To show this, we will show that  $a \cdot a \equiv 1 \pmod{p}$  with  $0 < a < p$  implies  $a = 1$  or  $a = p - 1$ .

$a^2 \equiv 1 \pmod{p}$  implies  $p|(a^2 - 1)$ , implying  $p|(a + 1)(a - 1)$ . By 2.27, this means either  $p|(a + 1)$  or  $p|(a - 1)$ . Since  $0 < a < p$ , the only possibilities for either of these is to set  $a = 1$  so that  $a - 1 = 0$  or  $a = p - 1$  so that  $a + 1 = p$ , both of which are divisible by  $p$ .  $\square$

**Exercise 4.39.** *Find all pairs of numbers  $a$  and  $b$  in  $\{2, 3, \dots, 11\}$  such that  $ab \equiv 1 \pmod{13}$ .*

$$2 \cdot 7 \equiv 1 \pmod{13}$$

$$3 \cdot 9 \equiv 1 \pmod{13}$$

$$4 \cdot 10 \equiv 1 \pmod{13}$$

$$5 \cdot 8 \equiv 1 \pmod{13}$$

$$6 \cdot 11 \equiv 1 \pmod{13}$$

**Theorem 4.40.** *If  $p$  is a prime larger than 2, then  $2 \cdot 3 \cdot 4 \cdots (p - 2) \equiv -1 \pmod{p}$ .*

*Proof.* Each term pairs up with its unique inverse to turn the product into a series of 1's multiplied together. The uniqueness part of 4.36 and the fact that none of these numbers are their own inverse (4.38) show that each number will have *exactly* one inverse in the rest of the product.  $\square$

**Theorem 4.41.** *If  $p$  is a prime, then  $(p - 1)! \equiv -1 \pmod{p}$ .*

*Proof.* Using 4.40, we see  $(p - 1)! \equiv 1 \cdot (2 \cdots (p - 2)) \cdot (p - 1) \equiv 1 \cdot 1 \cdot (-1) \equiv -1 \pmod{p}$ .  $\square$

**Theorem 4.42.** *If  $n$  is a natural number such that  $(n - 1)! \equiv -1 \pmod{n}$ , then  $n$  is prime.*

*Proof.* Say  $a$  is a factor of  $n$  with  $0 < a < n$ . Since  $(n - 1)! \equiv -1 \pmod{n}$ , we know  $n|((n - 1)! + 1)$ . Given  $a|n$ , this means  $a|((n - 1)! + 1)$ . However,  $a|(n - 1)!$  since  $a \leq n - 1$  and thus  $a$  is "included" in the factorial. Thus,  $a|1$ , implying  $a = 1$ .

We conclude the only factor of  $n$  between 0 and  $n$  is 1. In other words,  $n$  is prime.  $\square$

## 6 Chapter 6

### Lagrange's Theorem

**Theorem 6.1.** *Let  $f(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_0$  be a polynomial of degree  $n > 0$  with integer coefficients and assume  $a_n \neq 0$ . Then an integer  $r$  is a root of  $f(x)$  if and only if there exists a polynomial  $g(x)$  of degree  $n - 1$  with integer coefficients such that  $f(x) = (x - r)g(x)$ .*

*Proof.* To see that the existence of  $g(x)$  such that  $f(x) = (x - r)g(x)$  implies  $r$  is a root is easy: notice  $f(r) = (r - r)g(r) = 0 \cdot g(r) = 0$ .

The other direction requires some polynomial long division, which I won't Tex out because that would be a.) hell for me and b.) uninformative for the reader. Instead I will assert without evidence that  $f(x)/(x - r)$  simplifies out to  $a_n x^{n-1} + (a_n r + a_{n-1})x^{n-2} + \cdots + (a_n r^{n-1} + a_{n-1} r^{n-2} + \cdots + a_0) + a_n r^n + a_{n-1} r^{n-1} + \cdots + a_0$ , with the part from  $a_n r^n$  on being the remainder. Notice, then, that since  $f(r) = 0$ , the remainder is 0. Looking at the coefficients on the rest of the terms, we notice they're all made up of integers added and multiplied together, and thus must all be integers. Thus,  $f(x)/(x - r)$  is a satisfactory  $g(x)$  such that  $f(x) = (x - r)g(x)$ .  $\square$

**Theorem 6.2.** *Let  $f(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_0$  be a polynomial of degree  $n > 0$  with integer coefficients and  $a_n \neq 0$ . Let  $p$  be a prime number and  $r$  an integer. Then, if  $f(r) \equiv 0 \pmod{p}$ , there exists a polynomial  $g(x)$  of degree  $n - 1$  such that*

$$(x - r)g(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_1 x + b_0$$

where  $a_0 \equiv b_0 \pmod{p}$

*Proof.* We divide  $f(x)/(x - r)$  as above, but instead of noticing the remainder is 0 we notice the remainder is congruent to 0 modulo  $p$ . If we let the quotient (without the remainder) be  $g(x)$ , then we notice  $f(x) = (x - r)g(x) + R$ , where  $R$  is the remainder. Rearranging, we obtain  $(x - r)g(x) = f(x) - R = a_n x^n + \cdots + a_1 x + a_0 - R$ .

From here, we combine  $a_0 - R$  into one term  $b_0$ , noticing that since  $p|R$  we know  $a_0 \equiv b_0 \pmod{p}$ , and obtain  $(x - r)g(x) = a_n x^n + \cdots + a_1 x + b_0$ , and we're done.  $\square$

**Theorem 6.3.** *If  $p$  is a prime and  $f(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_0$  is a polynomial with integer coefficients and  $a_n \not\equiv 0 \pmod{p}$ , then  $f(x) \equiv 0 \pmod{p}$  has at most  $n$  non-congruent solutions modulo  $p$ .*

*Proof.* We will induct on  $n$ . Our base case is  $n = 0$ , in which we are trying to find solutions to  $a_0 \equiv 0 \pmod{p}$  where  $a_0 \not\equiv 0 \pmod{p}$ . Obviously there are 0 solutions to this.

Our induction hypothesis is that for  $m < n$ , any polynomial  $g(x) = a_m x^m + a_{m-1} x^{m-1} + \cdots + a_0$  has at most  $m$  non-congruent modulo  $p$  solutions to the equation  $g(x) \equiv 0 \pmod{p}$ . Our induction step hopes to show this property holds for  $n$ .

Say  $f(x) = a_n x^n + a_{n-1} x^{n-1} + \cdots + a_0$ . If the equation  $f(x) \equiv 0 \pmod{p}$  has no solutions, we're done, so we'll go ahead and assume it has one solution  $x = r$ . Then by 6.2 we find  $f(x) \equiv (x - r)g(x)$  for some  $g(x)$  of order less than  $n$ .

Notice that any solution  $k$  to  $f(x) \equiv 0 \pmod{p}$  finds  $f(k) \equiv (k - r) \cdot g(k) \equiv 0 \pmod{p}$ . In other words,  $p|(k - r)g(k)$ . By 2.27, either  $p|(k - r)$  (i.e.  $k \equiv r \pmod{p}$ ) or  $p|g(k)$  (i.e.  $g(k) \equiv 0 \pmod{p}$ ). Thus, *any solution to  $f(x) \equiv 0 \pmod{p}$  that is incongruent to  $r$  modulo  $p$  must also be a solution to  $g(x) \equiv 0 \pmod{p}$* . By our induction hypothesis, we know there are strictly less than  $n$  pairwise incongruent modulo  $p$  solutions to  $g(x) \equiv 0 \pmod{p}$ , so adding in  $r$  means we know there are *no more than*  $n$  pairwise incongruent modulo  $p$  solutions to  $f(x) \equiv 0 \pmod{p}$ .  $\square$

### Primitive roots

**Theorem 6.4.** *Suppose  $p$  is a prime and  $\text{ord}_p(a) = d$ . Then for each natural number  $i$  with  $(i, d) = 1$ ,  $\text{ord}_p(a^i) = d$ .*

*Proof.* To find  $k = \text{ord}_p(a^i)$ , we're looking for the smallest number such that  $(a^i)^k \equiv 0 \pmod{p}$ , or in other words  $a^{ik} \equiv 0 \pmod{p}$ . By 4.10, this is only the case when  $d|ik$ . Since  $(i, d) = 1$ , we know  $d|ik$  implies  $d|k$  (easily shown by 2.12. I swear to God we proved this somewhere, but this is like the 5th time I've gone to cite this imaginary theorem and I never find it). The smallest (natural)  $k$  such that  $d|k$  is  $d$ , so  $k = \text{ord}_p(a^i) = d$ .  $\square$

**Theorem 6.5.** For a prime  $p$  and a natural number  $d$ , at most  $\phi(d)$  incongruent integers modulo  $p$  have order  $d$  modulo  $p$ .

*Proof.* Either there is an integer with order  $d$ , or there isn't. If there isn't we're done, so let's assume there is one and call it  $a$ .

We will show that all numbers with order  $d$  are congruent to an integer of the form  $a^x$  where  $(d, x) = 1$  and  $x \leq d$ . As there are only  $\phi(d)$  possible values of  $x$ , this will mean that all integers with order  $d$  will be congruent to one of  $\phi(d)$  integers, and thus there can at most be  $\phi(d)$  incongruent integers with order  $d$ .

Let  $k$  be an integer with order  $d$ . Let  $A = \{a, a^2, a^3, \dots, a^d\}$  and  $K = \{k, k^2, k^3, \dots, k^d\}$ . By 4.8, we know both of these sets are pairwise incongruent. We also know that every element of  $A$  is a solution to the equation  $x^d - 1 \equiv 0 \pmod{p}$ , as  $(a^i)^d - 1 \equiv (a^d)^i - 1 \equiv 1^i - 1 \equiv 0 \pmod{p}$ . Similarly for  $K$ . By 6.3, there can only be  $d$  incongruent solutions to this equation. Thus, since  $A$  is full of  $d$  pairwise incongruent integers that are all solutions, it must contain one number congruent to each solution. Same with  $K$ . Thus, for any element of  $A$ , there must be a congruent element in  $K$ , and vice versa. Since  $k \in K$ , we know  $k = a^i$  for some  $i < d$ .

To see that  $(d, i) = 1$ , we notice that  $k^{d/(d,i)} \equiv a^{d \cdot \frac{i}{(d,i)}} \equiv 1 \pmod{p}$  (4.10) Since the order of  $k$  is  $d$ , we then know  $d/(d, i) \geq d$ , implying  $1 \geq (d, i)$ , which means  $(d, i) = 1$ .  $\square$

**Theorem 6.6.** Let  $p$  be a prime and suppose  $g$  is a primitive root modulo  $p$ . Then the set  $\{0, g, g^2, g^3, \dots, g^{p-1}\}$  forms a CRS modulo  $p$ .

*Proof.* Since this set has  $p$  elements, by 3.17, all we have to do to show this is a CRS is to show that the terms are pairwise incongruent modulo  $p$ .

None of the powers will ever be congruent to 0, because that would imply  $p|g^n$  which is impossible since no  $p$  can appear in the prime factorization of  $g^n$  (as if it did,  $g \equiv 0 \pmod{p}$  and then  $g$  has no order).

Say there are two integers  $i, j$  such that  $1 \leq i, j \leq p-1$  and  $g^i \equiv g^j \pmod{p}$ . Assume WLOG  $i > j$ . Then  $g^i \equiv g^j \pmod{p}$  implies  $g^{i-j} \cdot g^j \equiv 1 \cdot g^j \pmod{p}$ , which by 4.5 means  $g^{i-j} \equiv 1 \pmod{p}$ . By ??, this means  $(p-1)|(i-j)$ , but since  $0 \leq i-j \leq p-2$  the only multiple of  $p-1$  that the difference could be is 0, implying  $i = j$ . Thus, if two of the nonzero members of the set are congruent, they are the same element. In other words, they are pairwise incongruent modulo  $p$ .  $\square$

**Exercise 6.7.** For each of the primes  $p$  less than 20 find a primitive root and make a chart showing what powers of the primitive root give each of the natural numbers less than  $p$ .

2:  $1^1 \equiv 1$ .  
3:  $2^2 \equiv 1, 2^1 \equiv 2$ .  
5:  $3^4 \equiv 1, 3^3 \equiv 2, 3^1 \equiv 3, 3^2 \equiv 4$ .  
7:  $3^6 \equiv 1, 3^2 \equiv 2, 3^1 \equiv 3, 3^4 \equiv 4, 3^5 \equiv 5, 3^3 \equiv 6$ .  
11:  $2^{10} \equiv 1, 2^1 \equiv 2, 2^8 \equiv 3, 2^2 \equiv 4, 2^4 \equiv 5, 2^9 \equiv 6, 2^7 \equiv 7, 2^3 \equiv 8, 2^6 \equiv 9, 2^5 \equiv 10$ .  
13:  $2^{12} \equiv 1, 2^1 \equiv 2, 2^4 \equiv 3, 2^2 \equiv 4, 2^9 \equiv 5, 2^5 \equiv 6, 2^{11} \equiv 7, 2^3 \equiv 8, 2^8 \equiv 9, 2^{10} \equiv 10, 2^7 \equiv 11, 2^6 \equiv 12$ .  
17:  $3^{16} \equiv 1, 3^{11} \equiv 2, 3^1 \equiv 3, 3^{12} \equiv 4, 3^5 \equiv 5, 3^{15} \equiv 6, 3^{11} \equiv 7, 3^{10} \equiv 8, 3^2 \equiv 9, 3^3 \equiv 10, 3^7 \equiv 11, 3^{13} \equiv 12, 3^4 \equiv 13, 3^9 \equiv 14, 3^6 \equiv 15, 3^8 \equiv 16$ .  
19:  $2^{18} \equiv 1, 2^1 \equiv 2, 2^{13} \equiv 3, 2^2 \equiv 4, 2^{16} \equiv 5, 2^{14} \equiv 6, 2^6 \equiv 7, 2^3 \equiv 8, 2^8 \equiv 9, 2^{17} \equiv 10, 2^{12} \equiv 11, 2^{15} \equiv 12, 2^5 \equiv 13, 2^7 \equiv 14, 2^{11} \equiv 15, 2^4 \equiv 16, 2^{10} \equiv 17, 2^9 \equiv 18$ .

**Theorem 6.8.** Every prime  $p$  has a primitive root.

*Proof.* It says we'll come back to this one.  $\square$

**Exercise 6.9.** Consider the prime  $p = 13$ . For each divisor  $d = 1, 2, 3, 4, 6, 12$  of  $12 = p-1$ , mark which of the natural numbers in the set  $\{1, 2, 3, \dots, 12\}$  have order  $d$ .

Order 1: Just 1.  
Order 2: Just 12.  
Order 3: 3, 9.  
Order 4: 5, 8.  
Order 6: 4, 10.  
Order 12: 2, 6, 7, 11.

## Euler's $\phi$ -function and sums of divisors

**Exercise 6.10.** Compute each of the following sums

1.  $\sum_{d|6} \phi(d) = 1 + 1 + 2 + 2 = 6$
2.  $\sum_{d|10} \phi(d) = 1 + 1 + 4 + 4 = 10$
3.  $\sum_{d|24} \phi(d) = 1 + 1 + 2 + 2 + 2 + 4 + 4 + 8 = 24$
4.  $\sum_{d|36} \phi(d) = 1 + 1 + 2 + 2 + 2 + 6 + 4 + 6 + 12 = 36$
5.  $\sum_{d|27} \phi(d) = 1 + 2 + 6 + 18 = 27$

Make a sweeping conjecture about the sum of  $\phi(d)$  taken over all natural divisors of any natural number  $n$ .

**Paul's Conjecture 7.** For any natural number  $n$ ,

$$\sum_{d|n} \phi(d) = n$$

**Theorem 6.11.** If  $p$  is a prime, then

$$\sum_{d|p} \phi(d) = p$$

*Proof.*  $\sum_{d|p} \phi(d) = \phi(1) + \phi(p) = 1 + (p - 1) = p$ . □

**Theorem 6.12.** If  $p$  is a prime, then

$$\sum_{d|p^k} \phi(d) = p^k$$

*Proof.* First, notice  $\phi(p^i) = p^i - p^{i-1}$  for any natural  $i$ . This is because there are  $p^i$  natural numbers less than or equal to  $p^i$ , and 1 in every  $p$  of them is a multiple of  $p$  and thus not relatively prime (i.e.  $p^i/p = p^{i-1}$  of them are multiple of  $p$ ).

$$\sum_{d|p^k} \phi(d) = \sum_{i=0}^k \phi(p^i) = 1 + \sum_{i=1}^k (p^i - p^{i-1}) = p^k. \quad \square$$

**Theorem 6.13.** If  $p$  and  $q$  are two different primes, then

$$\sum_{d|pq} \phi(d) = pq$$

*Proof.* There are  $pq$  natural numbers less than or equal to  $pq$ . One in  $p$  are a multiple of  $p$ , one in  $q$  are a multiple of  $q$ , and the rest are relatively prime to  $pq$ . Thus  $\phi(pq) = pq - q - p + 1$  (the  $+1$  is because we subtracted out  $pq$  twice, once as a multiple of  $p$  and once as a multiple of  $q$ ).

$$\sum_{d|pq} \phi(d) = \phi(1) + \phi(p) + \phi(q) + \phi(pq) = 1 + (p - 1) + (q - 1) + (pq - q - p + 1) = pq \quad \square$$

**Theorem 6.14.** If  $n$  and  $m$  are relatively prime natural numbers, then

$$\left( \sum_{d|m} \phi(d) \right) \cdot \left( \sum_{d|n} \phi(d) \right) = \sum_{d|mn} \phi(d)$$

*Proof.*  $(\sum_{d|m} \phi(d)) \cdot (\sum_{d|n} \phi(d)) = \sum_{d_1|m} \sum_{d_2|n} \phi(d_1) \cdot \phi(d_2)$  by distribution. By 2.31, for every possible  $d_1$  and  $d_2$  we know  $(d_1, d_2) = 1$ . Thus, we can simplify the above as  $\sum_{d_1|m, d_2|n} \phi(d_1 \cdot d_2)$ .

Since  $n$  and  $m$  are relatively prime, every factor  $d$  of  $mn$  is a unique combination of some  $d_1|m$  and  $d_2|n$ , and vice versa. In other words, the set of factors of  $mn$  is the same as the set  $\{d_1 \cdot d_2 : d_1|m, d_2|n\}$ , by 2.12 (trust me). Thus, we can simplify further to find  $(\sum_{d|m} \phi(d)) \cdot (\sum_{d|n} \phi(d)) = \sum_{d|mn} \phi(d)$ . □

**Theorem 6.15.** If  $n$  is a natural number, then

$$\sum_{d|n} \phi(d) = n$$

*Proof.* By FTA, any  $n = p_1^{r_1} \cdot p_2^{r_2} \cdot \dots \cdot p_m^{r_m}$  for distinct primes  $p_1$  through  $p_m$  and natural numbers  $r_1$  through  $r_m$ . We will induct on  $m$ .

Our base case is  $m = 0$ , which is 6.12.

Our inductive hypothesis is that for all  $k < m$ , if  $n = p_1^{r_1} \cdot \dots \cdot p_k^{r_k}$  then  $\sum_{d|n} \phi(d) = n$ . Our inductive step must show that this holds for  $m$ .

Say  $n = p_1^{r_1} \cdot \dots \cdot p_{m-1}^{r_{m-1}} \cdot p_m^{r_m}$ . Let  $\eta = p_1^{r_1} \cdot \dots \cdot p_{m-1}^{r_{m-1}}$ . Notice by our inductive hypothesis that  $\sum_{d|\eta} \phi(d) = \eta$  and  $\sum_{d|p_m^{r_m}} \phi(d) = p_m^{r_m}$ . Also notice by 2.12 that  $(\eta, p_m^{r_m}) = 1$ . Then, by 6.14 we see  $n = \eta \cdot p_m^{r_m} = \left( \sum_{d|\eta} \phi(d) \right) \cdot \left( \sum_{d|p_m^{r_m}} \phi(d) \right) = \sum_{d|\eta \cdot p_m^{r_m}} \phi(d) = \sum_{d|n} \phi(d)$ .

Removing the middle steps, we find  $n = \sum_{d|n} \phi(d)$ . □

**Exercise 6.16.** For a natural number  $n$  consider the fractions

$$\frac{1}{n}, \frac{2}{n}, \frac{3}{n}, \dots, \frac{n}{n},$$

all written in reduced form. Try to find a natural one-to-one correspondence between the reduced fractions and the number  $\phi(d)$  for  $d|n$ . Show how that observation provides a very clever proof to the preceding theorem.

*Proof.* For any  $d|n$ , there are  $\phi(d)$  fractions that have  $d$  as their denominator in simplest form.

Notice that for any  $d|n$ , the list of fractions above will contain all of  $\frac{1}{d}, \frac{2}{d}, \dots, \frac{d}{d}$ . This is because for any  $u \leq d$ , we know  $\frac{u}{d} \cdot (n/d) = \frac{u(n/d)}{n}$ , and  $u(n/d) = n(u/d) \leq n$  because  $u/d \leq 1$ .

Thus, there are  $d$  “candidates” for fractions with  $d$  as their denominator in simplest form. Notice that since simplest form is when the numerator and denominator are relatively prime, these fractions do have  $d$  as their denominator in simplest form exactly when the numerator is relatively prime to  $d$ . Since the numerator can be any value from 1 to  $d$ , this means the number of fractions with  $d$  as the denominator in simplest form is equal to the number of naturals from 1 to  $d$  that are relatively prime to  $d$ , or  $\phi(d)$ .

Notice, then, that every fraction in the series  $\frac{1}{n}, \dots, \frac{n}{n}$  has to have a simplest form (with some divisor of  $n$  as the denominator). Thus, if we add up the number of fractions with  $d$  as their denominator in simplest form for all  $d|n$ , we’ll get the number of fractions (which is  $n$ , since there are  $n$  possibilities for the numerator). In other words, since  $\phi(d)$  is the number of fractions with  $d$  in their denominator in simplest form, we’re saying  $n = \sum_{d|n} \phi(d)$ . □

**Theorem 6.17.** Every prime  $p$  has  $\phi(p-1)$  primitive roots.

*Proof.* It’s the last week of high school, this is going to be pretty informal.

There are  $p-1$  numbers less than  $p$  that all have to have some order. Since we know for any  $k$  that  $k^{p-1} \equiv 1 \pmod{p}$  by 4.15 (Fermat’s Little), we know by 4.10 that the order of every number needs to divide  $p-1$ . Thus, the possible orders are the divisors of  $p-1$ . For each divisor  $d$ , there are  $\phi(d)$  “slots” (as only  $\phi(d)$  incongruent numbers can have order  $d$  by 6.5). Thus, the total number of “slots” is  $\sum_{d|p-1} \phi(d)$ , which by 6.15 means there are  $p-1$  slots. Since there are  $p-1$  numbers, this means every slot must be filled: there are  $\phi(p-1)$  “slots” for numbers with order  $p-1$ , and so since all are filled there must be  $\phi(p-1)$  numbers with order  $p-1$ , i.e.  $\phi(p-1)$  primitive roots of  $p$ . □

## Euler’s $\phi$ -function is multiplicative

**Exercise 6.18.** Make a conjecture about the value  $\phi(p)$  for a prime  $p$ . Prove your conjecture.

**Paul’s Conjecture 8.** For any prime  $p$ ,  $\phi(p) = p-1$

*Proof.* There are  $p-1$  numbers less than  $p$  and all of them are relatively prime to  $p$  since  $p$  is prime. □

**Exercise 6.19.** Make a conjecture about the value  $\phi(p^k)$  for a prime  $p$  and natural numbers  $k$ . Prove your conjecture.

**Paul’s Conjecture 9.** If  $p$  is a prime and  $k$  is a natural number, then  $\phi(p^k) = p^k - p^{k-1}$ .

*Proof.* There are  $p^k$  natural numbers less than or equal to  $p^k$ . Of those, 1 in every  $p$  have a  $p$  in their prime factorization and thus are not relatively prime to  $p^k$ , so we need to subtract the  $p^k/p = p^{k-1}$  non-relatively-prime numbers from that set, leaving us with  $p^k - p^{k-1}$  remaining numbers. □

**Theorem 6.20.** If  $n$  is a natural number and  $A$  is a CRS modulo  $n$ , then the number of numbers in  $A$  that are relatively prime to  $n$  is equal to  $\phi(n)$ .

*Proof.* Let  $a \in A$  and  $k$  be the unique member of the CCRS modulo  $n$  such that  $a \equiv k \pmod{n}$ . We find  $(a, n)|n$  and thus  $(a, n)|(a - k)$ , and thus  $(a, n)|k$ . Similarly, we find  $(k, n)|a$ . Thus,  $(a, n) = (k, n)$ , implying that  $a$  is relatively prime if and only if  $k$  is.

Since we can cast each member of  $A$  uniquely to the CCRS this way, we find counting the number of numbers in  $A$  that are relatively prime to  $n$  is the same as counting the number of numbers in the CCRS that are relatively prime to  $n$ . Since the CCRS is just  $\{0, 1, \dots, n-1\}$ , it's clear that the latter is  $\phi(n)$ , and thus so is the number of numbers in  $A$  that are relatively prime to  $n$ .  $\square$

**Theorem 6.21.** *If  $n$  is a natural number,  $k$  is an integer, and  $m$  is an integer relatively prime to  $n$ , then the set of  $n$  integers*

$$\{k, k+m, k+2m, k+3m, \dots, k+(n-1)m\}$$

*is a complete residue system modulo  $n$ .*

*Proof.* By 3.17, we merely need to show the constituents of this set are incongruent modulo  $n$ , since there are clearly  $n$  elements.

Say  $k+im \equiv k+jm \pmod{n}$ . This implies  $n|(k+im - (k+jm))$ , implying  $n|(im - jm)$  or  $n|m(i-j)$ . Since  $(n, m) = 1$ , we cite 1.41 to conclude  $n|i-j$ . Since  $0 \leq i, j \leq n-1$ , we know  $-n+1 \leq i-j \leq n-1$ , and the only number in that range divided by  $n$  is 0, so  $i=j$ .

Thus, two separate elements (i.e. two elements such that  $i \neq j$ ) cannot be congruent modulo  $n$ , showing the set is a CRS.  $\square$

**Exercise 6.22.** *Consider the relatively prime natural numbers 9 and 4. Write down all the natural numbers less than or equal to  $36 = 9 \cdot 4$  in a rectangular array that is 9 wide and 4 high. Then circle those numbers in that array that are relatively prime to 36. Try some other examples using relatively prime natural numbers.*

I'm... gonna be honest, I did this and it was not enlightening. I have no idea what's going on.

OH WAIT the columns all have the same number of circles! Cool!

**Theorem 6.23.** *If  $n$  and  $m$  are relatively prime natural numbers, then*

$$\phi(mn) = \phi(m)\phi(n)$$

*Proof.* Take any number  $a \leq mn$ . By division algorithm,  $a = k + qm$  for some  $0 \leq k < m$ . We're going to make a slight tweak: If  $a = 0 + qm$ , instead write it as  $a = m + (q-1)m$ , so that  $0 < k \leq m$ .

By 1.43, if  $(a, m) = 1$  and  $(a, n) = 1$  then  $(a, mn) = 1$ . The opposite is also true since  $(a, m)|(a, mn)$ , so if  $(a, mn) = 1$  then  $(a, m) = 1$  (and  $(a, n) = 1$ ).

Thus, the only way for  $a = k + qm$  to be relatively prime to  $mn$  is if  $(a, m) = 1$  and  $(a, n) = 1$ .

We notice  $(a, m) = 1$  if and only if  $(k, m) = 1$  (as  $(a, m)|k + qm$  implies  $(a, m)|k$  so  $(a, m)|(k, m)$  and  $(k, m)|k$  implies  $(k, m)|k + qm$  and thus  $(k, m)|a$  so  $(k, m)|(a, m)$ ).

There are thus  $\phi(m)$  possibilities for  $k$ . For each of these, we examine the set  $\{k, k+m, \dots, k+(n-1)m$ . By 6.21, this is a CRS modulo  $n$ , and by 6.20 that means there are exactly  $\phi(n)$  elements of this set that are relatively prime to  $n$ .

Thus, there are  $\phi(m)$  sets that each have  $\phi(n)$  numbers that are relatively prime to both  $m$  and  $n$  (and thus relatively prime to  $mn$ ). Thus, the total number of numbers less than  $mn$  that are relatively prime to  $mn$  is  $\phi(mn) = \phi(m) \cdot \phi(n)$ .  $\square$

**Exercise 6.24.** *Compute each of the following.*

1.  $\phi(3) = 2$
2.  $\phi(5) = 4$
3.  $\phi(15) = \phi(3) \cdot \phi(5) = 8$
4.  $\phi(45) = \phi(9) \cdot \phi(5) = 24$
5.  $\phi(98) = \phi(2) \cdot \phi(7^2) = 42$
6.  $\phi(5^6 11^4 17^{10}) = \phi(5^6) \cdot \phi(11^4) \cdot \phi(17^{10}) = 5^5 11^3 17^9 \cdot 4 \cdot 10 \cdot 16 = 2^7 5^6 11^3 17^9$

**Question 6.25.** *To what power would you raise 15 to be certain that you would get an answer that is congruent to 1 modulo 98? Why?*

By 4.32 (Euler's theorem), 42.

**Question 6.26.** *How many primitive roots does the prime 251 have?*

By 6.17, it has  $\phi(250) = \phi(2) \cdot \phi(5^3) = 1 \cdot 5^3 - 5^2 = 100$  primitive roots.
